## PORTRAIT OF DR. THADDEUS WILLIAM HARRIS.

Originally engraved on steel by Halpin, after a photograph in the possession of the family, for the edition of Harris's "Entomological Correspondence," published in 1869 by the Boston Society of Natural Mistory. The plate having been lost in the Boston fire of 1872 , a photogravmre plate has been prepared and printed by A. Wr. Elson $\mathbb{\&}$ Co. from an artist's proof of the original steel-plate.

# EASTERN UNITED STATES AND CANADA 

NOT FOUND IN NEW ENGLAND.

You nymphs, calld Naiads, of the windring brooks, With your sedged crowns and ever-harmless looks, Leave your crisp channels and on this green laud Auswer your summons.

Shakespeare. - The Tempest.

## NYMPHALIDAE.

## SUBFAMILY SATYRINAE.

OENEIS HÜBNER.

## OENEIS MACOUNII.

Chionobas macounii Edwards, Canad. ent., Ont., 1888, 8ā (1889); Trip to Nepigon, 12 svil: 74.75 (188j̄); -Fletcher, Rep. ent. soc.
(1889).

Imago. Head corered above with black brown scales and intermingled white hairs and elongated scales. Palpi heavily fringed with blackish hairs. Antennae luteous, clearer on the cluh than on the stalk; the latter sparsely flecked above with blackish brown scales with intermingled white ones. Thorax sparsely clothed above with pale brown hairs, below with black hairs; the femora corered with black hairs and scales, excepting at the tips which, with the luteo-castaneous legs, are pretty heavily corered with yellowish white scales; all the spines luteo-castancous; claws slightly reddish.

Wings above brownish, sometimes burnt orange, varying in depth of tint in both males and females, some being much cmbrowned, others much paler; all the wings margined excepting on the inner edge with a broad blackish brown band, slightly broader on the fore wings than on the hind wings; all the nervures marked in brown. Fore zoings with a narrow, arcuate, blackish brown stripe depending from the costal border, bordering the outer edge of the cell, extending outward slightly on the last median nervule; all generally obsolete in the male, distinct in the femalc; a roundish oral black spot with a white pupil in the middle of the lower subcostal and median interspaces, in the former occupying the whole width of the interspace, occasionally blind, especially in the median interspace; besides this, in the same row with them, there are occasionally found similar ocelli, smaller and almost inrariably blind in the upper median and subcosto-median interspaces, especially the former; these last are
generally absent from the male, geuerally present in the female, and in one female hefore me which has no spot in the subcosto-median interspace there is a large ocellus in the next to the lowest subcostal interspace almost as large as the one below it and marked with a slender median longitudinal line of white scales. Normally the male has no sexual streak. In the hind wings a similar, smaller, round, generally whitepupiled ocellus is found a little before the middle of the outer half of the lower median interspace.

Beneatl: Fore wings of the same ground color as above, perbaps a little paler, the costal margin with a broad brown border, finely irrorate, excepting at the tip, with black and white, the tip ashen flecked with black; the outer margin with a brown border, narrowing dowuward; the same dark bar depends from the costal margin at the outer edge of the cell, again more distinct in the female than in the male, but in addition to this there is, at least in the female, a very broad, obscure, median band washed in brown, broader than the width of the cell, crossing the whole wing and bent at the median nervure; this is generally almost entirely absent from the male; the ocelli of the upper surface are almost exactly repeated beneath, but in the exceptioual female noted, there is no ocellus in the next to the lowest subcostal interspace. Hind wings varying very mnch in general color but the general effect is an ashen gray, deeper in some parts of the wing than in others and especially deepest along the outer margin and more especially in an exceedingly broad mesial or pre-mesial belt of irregular outline, more or less sinuous, approaching the base at the subcostal nervure, and the outer margin at the tip of the cell; this is usually more distinct in the female than in the male, but is never entirely absent; the ashen tints prevail along the costal border, especially on either side of the mesial belt, but in some specimens it covers the largest part of the wing; the broad mesial belt is more distinct at its margins than elsewhere and in some individuals this is almost the ouly token of its presence; the intermingling of colors on the wing is largely in the presence of short, transverse, tremulons threads of blackish brown on the paler brown ground; this is most distinct along the inner margin of the wing; fringe of all the wings black, narrowly interrupted in the middle of the interspaces with white; the extreme outer edge with a thread of black upon both wings; the only mark of an ocellus on the under surface is an extremely minute one, usually pupiled, in the same place as abore, but a similar oue is sometimes seen in the lower subcostal interspace where it is sometimes not pupiled, and the ocellus is more commonly preseut in the female than in the male. Expanse of wings $\delta, 58-63 \mathrm{~mm} ; ; \%, 64-69 \mathrm{~mm}$.

The following account of the early stages is given by Fletcher (loc. cit.) :-
Egg. Large, globular; rather higher than broad, flattened at top and bottom; coarsely ribbed from top to bottom with about twenty ribs, a few of which divide at the hottom; between these are zigzag furrows crossing from rib to rib. Eggs laid on 6th July hatched on 26 th , the larva eating a narrow strip from the egg shell round the top and theu pushing its way out leaving the egg-shell almost intact. Very few of the larvae ate their egg shells.

Caterpillar. First stage. The young larvae are larger [ 3 mm .] than those of jutta, and have the heads more hairy; there are also a few black spots about the head which do not occur in jutta. Upon the head and body of both species are some curious mammiform hairs. The larvae are very sluggish, and seem to like to perch upon dead leaves of grass during the daytime.

Seconl stage. The first moult took place about 18 th August, after which the larvae were [ 8.4 mm. ] in length. Head round, flattened in front, greenish white, punctured, hearing on each side three stripes continuous with the stripes of the body and composed of the hack hollows of the roughened surface; the two upper stripes joiu at their tips just above the ocelli. General colour, dull, glaucous, greenish white, with brown stripes. On [the first thoracic] segment, just above and anterior to the spiracles is, on each side in both this species and jutta, oue long thoracic bristle curved forward. Food, Carices and grasses.

Third stage. Teu days after moult. General appearance greenish gray, with red-
dish brown stripes which are deeper in color posteriorly. Head greenish white and deeply pitted; mandibles darkened at their tips; ocelli black. Marked on each side with three narrowing stripes of black, which are continuations of the markings on the body, and consist of the blackened pits of the surface of the head; the dorsal stripe divides and sends a branch down on each side of the frontal triangle; the other two stripes on each side of the head are extensions of the subdorsal stripe and lateral band of the body; they converge but do not quite meet above the ocelli, which the lower reaches.

The markings of the body are as follows : a conspicuous, narrow, mediodorsal stripe terminating betweeu the anal horns, and beariug in the middle a narrow, white, broken line; below this a wide, white, subdorsal space, bearing in the middle a narrow, subdorsal line, with a waved, threadlike line on each side of it, and about half way to the edge of the subdorsal space; a conspicuous lateral baud, which is pale in the centre; a stigmatal stripe, pale but clearly defned, and showing the supra-and infrastigmatal spaces above and below as clear greeuish white liues; beneath the substigmatal fold is another brown band, with disconnected pale spaces in the ceutre. Spiracles small and black, but surrounded by a pale ring. Thoracic feet and prolegs greenish white aud translucent. The whole body sparsely covered with short, clavate hairs. The aual horns half the length of the anal segment ancl bent upwards. Length, 12 mm . (Third stage communicated by J. Fletcher.)

Exeepting Morley, at the eastern base of the Rocky Mountains of Alberta, Nepigon, at the northern extremity of Lake Superior, is the only known locality for this species, which must, nevertheless, have a wide distribution. It is single brooded, appearing early in July. The eggs hateh in about three weeks, slightly sooner if transported to the south, the eaterpillars live as long or longer in their first stage, moult for the first time in the latter half of August and winter iu the second stage. One carried through the winter by Mr. Fleteher revived April 25 and moulted May 15. The caterpillars are exeeedingly sluggish, and in their first stage larger and more brilliantly marked than Oeneis jutta. Their latest ehanges have not been observed, though eggs distributed by Mr. Fleteher and myself in the summer of 1888 will, it is hoped, secure its further history. These are laid freely on grasses.

The butterfly has a very different flight from that of some species of the genus and belongs properly to a distinct section from Oe. semidea, and one to which Oe. jutta also belongs; its movements are swift and, notwithstanding their Satyrid character, are not altogether unlike those of Basilarchia archippus, which on the wing it much resembles. The eggs are subject to the attack of Triehogramma intermedium (89:8) whieh Mr. Fletcher reared, and the mortality among the growing eaterpillars, from whatever cause, is very great ; these feed readily upon both grasses and sedges.

## OENEIS CALAIS.

[^0]Imago. Head, thorax and abdomen black, with ochraceous hairs. Antenuae reddish yellow, annulated, especially above, with reddish brown; club reddish brown, black
tipped. Palpi with ochre yellow bairs, mingled with longer black hairs, which latter are especially prominent beueath and at the tip. Femora dusky; tibiae and tarsi pale yellow.

Wings abore deep ochraceous brown, flecked with black on the basal half and along the costal and outer margin of both wings, eye-like spots before the margin, beneath marbled with ochraccous and brown; fringe dark brown, interrupted in the interspaces with grayish white. Fore wings ochraceous brown, the costal border marbled with black and grayish white, distinct next the base, forming a dark grayish band toward the tip, continned more broadly around the outer to the inner border as a dark brown band, the inner edge slightly cremulated, the outer elge distinctly black; a very broad band clouded with black, darkest at the borders, and somewhat tinged with ochraccons in the middle, crosses the middle of the wing; the nervure closing the cell is distinctly and narrowly edged with black; the outer border of the band starts from the dusky costal border beyond the cell at right angles to the last branch of the nervure, projecting outwards as a short tooth upon this nervure, is there bent at right angles toward the base, and immediately thereafter bends again aud passes in broad crenations to the inner and subparallel to the outer border; the inner border of the band crosses the cell irregularly between the origin of the first and second median nervules and nearer the latter; below the cell, it passes from the origin of the first median nervule parallel to the costal border, but is lost before reaching the inner border. Between this band and the base the ochraceous is considerably flecked with brownish atoms, less distinctly next the band; in the broad ochraceous band next the outer border, occupying the space left between the two clark bands mentioned, are situated in the lowest subcostal, subcosto-median, and the lower median interspaces, large, roundish, inclined to be pyriform, blind, eye-like spots, that in the subcosto-median interspace a little smaller and rounder. Hind wings: Basal portion to the extremity of the cell fuscous, largely tinged with dull ochraceous, except above the cell; toward the base very indistinctly marked with faint fuscous and ochraceous; the outer limit of this fuscous basal portion is that of the outside of the middle band beneath; the outer border of the wing from the tip of the first subcostal nervale to the anal angle has a narrow dusky band, narrower than that of the fore wings, blackish on the inside where it is very slightly crenulate, paler along the middle, the edge black again; the marbling of the under surface shows indistinctly through upon the broad, ochraceons brown band which occupies most of the outer half of the wing, and in the interspace beyond the first and second median nervules is a round, black, blind, eye-like spot, smaller than any of those of the fore wings.

Beneath: Fore wings considerably paler than above; the middle band of the upper surface distinct only at the borders, the lower portion of the outer border straight, the middle space being of the ground color, with transverse, slightly wavy streaks, especially in the cell, of blackish brown; similar frequent streaks in the cell between the band and the base, the costal edge distinctly marbled with black and grayish white from base to apex, over which latter portion it is more diffused, though scarcely reaching the mediosubmedian interspace, except next the outer border, where ic exteuds at least to the third median nervule, and is bordered toward the base by a narrow band formed of continuous shallow lunules reaching neither the costal nor the inner border; next to which is a broad, ochraccons band, with infrequent transverse streaks of reddish brown, which never cross the nervures; the eyes as above, though more ovoid in form, and that of the lower median interspace very indistinctly white pupiled. Hind wings marbled with transverse bars and streaks of blackish brown and grayish white, tinged with pale ochraceous brown in the outer half of the wing, and with darker ochraceous brown in the middle of the band; at the base the bars are larger and about equally divided; in the band the darker ones are clustered along the borders so as to be continuous at the extreme border; in the outer half the marbling is pretty uniform, though less tinged with ochraceons next the middle band, the lighter colors prevailing throughout this portion; midway between the band and the outer border very inclistinct pale yellowish white spots in the interspaces; the eye reduced to an indistinct, small, round, black spot; the outer borcler narrowly edged with black, not extending to either angle, a small white spot situated
upon it in the interspaces; the inner border of the middle band is formed of a series of right angles from the costal border till it has passed the median nervure; in the space abore the cell it forms a right angle whose limbs are equal, projecting borderwards, in the cell one whose limbs are mequal projecting basewards, the short limb being the contimation of that of the interspace above, extending to the middle of the cell, whence it is directed to the origin of the first median nervule, is again bent here at right angles before reaching it, and continues to the internal nervare, whence it extends, bent slightly borderwards, to the imuer margin; the outer border of the band starting from the costal border of the wing passes in one arch to the second subcostal nervule, here extends borderwards to the middle of the interspace opposite the extremity of the cell, and thence moves in a gradnal crenulated curve, passing jnst beyond the extremity of the cell to the imer border; the band is broader than in most species of the genus, and is especially so on the median nervures; the nervures are all distinctly flecked with white. Expanse of wings, 56 mm .

This butterfly appears to be confined to the high northern regions of the eastern half of the continent, being thus far known only from Rupert House* at the southeastern extremity of Hudson Bay and Carbonear, Newfoundland. Nothing is known of its history or seasons.

## CERCYONIS SPEYER.

## CERCYONIS PEGALA.

Papilio pegala Fabr., Ent. syst., iii: 230 (1793).

Sutyrus pegala Edw., Can. ent., xii:51-54 (1850) ; French, Butt. east. U. S., 242-243 (1856).

Cercyonis pegala Scudl., Bull. Buff, soc. nat. se., ii: 241 (1875).
Satyrus alope form pegate Smith, Bnll. lbrookl, ent. soc., vi : 128-129 (1884).

Imago. Hlead covered with mouse brown and gray hairs, the fringe of the palpi with many black ones; the antennal stalk black brown, narrowly aumnlate at the base of the joints with white, the club luteous, a little infuscated.

Wings above dark brown with a chocolate tinge; the onter boider with a faint, slender, pre-marginal, somewhat lunulate, narrow, blackish brown stripe, not greatly darker than the ground, and on the fore wings limiting in the lower half of the wing an exceedingly broat orange yellow band which traverses the wing beyond the middle, of nearly equal width throurhout and extending from the costal to the submedian nerrure, its inner margin gently arcuate or bent in the middle and lying wholly beyond the cell; in the npper onter corner of this broad belt and occnpying the whole width of the lowest subcostal interspace is a large, round, black spot with a blurred margin, containing a distinct, though small cacrulean blue pupil; in addition there is often in the middle of the lower median interspace a black point, or sometimes an incomplete ocellus. On the hind wings there is no such yellow bauch, but at a corresponding point of the lower median interspace, that is, a little beyond the middle of the interspace, is a black ocellus with a brownish yellow areola and a blue pupil; the areola sometimes obsolete, the whole nearly or quite as large as the permanent ocellus of the fore wing; fringe of all the wings of the ground color but on the lower portion of the outer margin of the fore wiugs alittle paler; in all the wings preceded by a delicate black line at the extreme base of the fringe, and this, on the hind wings, by a pale brown line of similar width.

[^1]which flows into Hudson Bay from the opposite direction. Drexel was the collector.

Beneath, the grouncl color is paler than above, the basal half of all the wings somewhat uniformly but irregnlarly striate with short, blackish brown, transverse striae having thread-like terminations, pretty equally distributed; the pre-marginal line of the upper surface is repeated beneath on the fore wings as a nearly straight and connected stripe, approaching the border on the lower half of the wing, crenulate above; on the hind wings usually more vague, broken into separate bars in the succeeding interspaces on the upper half of the wing, continuons only on the lower half; on both wings, but especially upon the hinder, followed withont by more or less ashen tints; on the fore wings the band of the upper surface is repeated but is much more pallid; the upper ocellus freguently has a distinct yellow anmus edged with a blackish brown incomplete areola, distinct, if at all, only above; the interior edge of the band is limited more distinctly beneath by a blackish brown edging and bere has a sinuate direction, the lower half marked by the middle median uervule being removed inward somewhat beyond the upper half; a similar mesial stripe, similar in tint, width and irregularity, crosses the hind wing so as to mark off in a very vague and indistinct way a broad, extra-mesial band upon the hind wings like that upon the fore wing, only that it has no yellow coloring, and crossing the middle of this broad band is an irregular series of large, roundish or long oval, velvety black ocelli, nearly always with a narrow yellow aunulns, surrounded by a broader and vaguer black brown areola, pupiled with a dot or more commonly a longitudinal streak or oval patch of caerulean blue; one of these ocelli occurs in every or nearly every interspace from the upper subcostal to the medio-submedian, that in the upper median being more frequently than any of the others blind or sub-obsolete, those in the lower subcostal and lower median interspaces being invariably the largest and as large as the large ocellus of the fore wing. Fringe of wings pale brown, the outer edge of the wings themselves marked by a blackish brown line, preceded by a line of similar width varying from white through ashen gray to brown in different individuals. Expanse of wings, $60-65 \mathrm{~mm}$.
The male bears upon the upper wing a broad, oblique patch of dead brown matted scales crossing the middle of the lower half of the wing, its outer margin parallel to the onter border, its inner subparallel to the costal border, so that it broadens as it passes from above downward, being found principally in the lower median and mediosubmedian interspaces near the base of the former but not reaching it, and accompanied by a small patch in the upper mediau interspace and a slightly larger one in the submedio-internal interspace.
The extent of this patch of scales separates the male noticeably from Cercyonis alope, from which it is usually to be distinguished by the absence of the lower ocellus of the extra-mesial band of the fore wing and the invariable presence of an ocellus on the upper surface of the hind wings.

Very common in the southern half of the states bordering the Gulf of Mexico, at least east of the Mississippi River, this butterfly is oceasionally found at relatively ligh northern latitudes, but only along the sea coast, having been found as far as ceutral New Jersey, where indeed, it is not uncommon.

No statements have been published regarding its history and seasons, so far as I have noted, except the remark by French to the effect that the caterpillar "is said to be gray, with one broad and one narrow white band. The food plant is coarse wild grass."

From the notes given by Edwards from different observers, it is evident that the butterfly is peculiarly a butterfly of the pine barrens, fond of hot sandy exposures, but seldom seen in open fields and given to alighting on erect tree trunks, especially of pines.

## COENONYMPHA HÜBNER.

Coenonympha Hübn., Verz. bek. schmett., ti5 Chortobius Guen., Doubl., List. Brit. Lep., (181 (i). 2.l ed. (18099).

Imago. Head not large, broadly tumid and protuberant in front, especially below, above much depressed, transversely and deeply sulcate in front of the antennae, the whole face slightly broader than ligh. Antennae decply inserted, the stalk of each scarcely nearer the side of the eye than jts neighbor, very slender, abont as long as the abdomen, composed of about thirty-three or thirty-four joints of which about eleven form the distinct club, tricarinate beneath, only the middle carina distinct, which increases gradually in size on the first three or four joints, beyond which it is equal, more than twice as stont as the stalk, terminating by the naked apical two joints in an abruptly rounded tip; in the middle of the stalk the joints are three times as long as broad, in the middle of the club the reverse. Palpi very slender and long, heavily fringed in a compressed plane beneath, the last joint excessively slender and unusually long, being fully half as long as the middle joint though scarcely a third its diameter. Eyes pretty large, full, naked.

Form of wings much as in Neonympha, with which it agrees in neuration, except in wanting the precostal nervure of the hind wings, beyond the merest spur, arising beyond and not at the divarication of the costal and subcostal nervures.

Fore legs excessively small, the tibiae not one-third the length of the hind tibiae; tarsi not one-half so long as the tibia, composed in the nale apparently of a single unarmed joint. flind tibiae slightly longer than hind femora. Legs cylindrical, a little flattened beneath; tibiae and tarsi divided, clothed and armed almost exactly as in Neonympha.

Clasps of mate abdominal appendages forming exceedingly slender, straight, elongate blades.

Egg. Broadly trnncate pyriform in slape, broadest near the middle of the basal half, above the broadest portion with numerous slightly elevated, vertical ribs united by tolerably frequent cross lines and terminating at the rim of the summit which is two-thirds as broad as the egg; below broadly convex.

Caterpillar at birth. Head large, rounded, with a dozen clubbed bristles like those of body on each hemisphere, symmetrically disposed. Body tapering slightly and with great regularity from the head to the tail, the last segment with two posterior, conical projections, one on either side. Several series of short, equal, rather coarse, clubbed bristles, not half so long as the segments, seated on small papillae, arranged in anterior subdorsal, posterior supralateral and median laterostigmatal series, one to a segment on all the segments, slightly altered on the thoracic, and a ventro-stigmatal series, two to a segment on the abdominal, one to a segment on the thoracic segments.

Mature caterpillar. Very long and slencler, the head rounded and barely broader than the body, the latter miform, tapering a very little on the terminal abdominal segments, clothed with the briefest possible pile, consisting of minute hairs on minute, profusely scattered papillae; abdominal segments divided into six sections of which all but the anterior section are equal, that almost twice as large as the others. Last abdominal segment with terminal forks shorter or no longer than the body of the last segment. Prolegs very short.

Chrysalis. Closely resembling that of Cercyonis, but much shorter and with fuller outlines.

Coenonympha contains a goodly number of species, all of which are found in the north temperate zone and particularly in the higher latitudes or altitudes. It is also far more richly represented in the Old World than in the New and in the latter is almost altogether confined to the western
half of the eontinent; indeed the species here described is the single one whieh is found in the eastern half and this extends aeross the continent.

The butterflies are weak winged insects of delieate texture and generally feeble and often vaguely defined markinge, usually of some shade of buff; they belong to the first section of Satyrid genera as defined in the present work, the eggs being vertically ribbed and eross lined excepting at base, the young caterpillar having bent euticular appendages, here very short, the mature eaterpillar a smoothly rounded head unerowned by projections, and with short tails, the ehrysalis a blunt anterior extremity, and the butterfly an angulate, inferiorly produced, outer extremity to the cell in the fore wings.

Notwithstanding that the genns is so much better developed in Europe than in Ameriea and in America is almost absolutely confined to the west, it was reserved for the indefatigable Edwards of West Virginia to give us our first knowledge of its early stages.

## COENONYMPHA INORNATA.

## Coenonympha inornate Edw., Proe. acad. nat. sc. Philad., 1861, 163 (1861).

Imago. Head covered with pale brownish yellow scales and hairs; palpi the same with a few scattered black ones; antennae clay brown, hearily flecked abore with brownish, excepting generally at the extreme base of the joints.

Upper surface of the wings pale yellow buff, sometimes nearly uniform, at other times with the markings of the under surface showing through, especially where these are heavy; fringe concolorous with the surface. Beneath, the same ground color as above, at least upon the fore wings, but the basal half or three-fifths of the hind wings heavily or lightly begrimed with a more or less dense sprinkling of black scales; the same are also found at the extreme loase of the fore wings, and to a very slight extent just beyond the middle of the wing upon the costal border; an extra-mesial, pallid or white band, with somewhat irregular contonr, crosses the fore wings from the middle of the outer two-thirds of the costal border toward a point just within the termination of the inner margin; it is distinctly edged only upon the inner side, where the wing is slightly darker than elsewhere; it is of varying length and depth, sometimes very obscure; there is sometimes in the first inferior subcostal interspace, midway between the cell and the margin, or rather nearer the latter, a minute, white-pupiled, round black spot. Hind wings with a similar but more irregular and tortuous extramesial, pallid or white stripe of irregular width, being widest beyond the cell, the onter extremity of which it turns inward to meet. The outer margin of all the wings lined with a fine black thread. Expanse of wings, $31-36 \mathrm{~mm}$.

From drawings by Gosse, Edwards finds this species occurring at Carbonear, Newfoundland. Excepting for this occurrence, the butterfly has not been taken east of Lake Winnipeg, having always been supposed to be a northern species of the western half of the continent, where it oecurs not only in British Ameriea, as far as Vaneouver Island and at Calgary and Edmonton (Geddes), but in Montana. Nothing is known of its transformations and seasons, exeepting that in Newfoundland Gosse took it in July and August.

## NEONYMPHA HÜBNER.

## NEONYMPHA CORNELIUS.

> I'apilio cornelius Fabr., ent. syst., iii: 220 (1793).
> Neonympha comelius Scudd., Bull. Buff. soc. nat. sc., ii : $24(1875)$.
> Neonympha gemma Hübn., Zutr. samml. exot. schmett., i: 8 , figs. $7-8$ (1818);-French,

Butt. east. U. S., 235-237 (1886). Sat!̣rus gemma Boislo-LeC., Lêp. amér. sept., pl. 62, fiys. 1-5 (i833).

Coenonympha gemma Edw., Can, ent., xi: 31-3á (1879).

Imago. Head covered with mingled dark brown, pallid and pale lateous hairs ; the palpi with mumerons longer or shorter black scales and hairs, especially above and below, leaving a very pale yellowish line along the outer and inner edge; the inside of the long inferior fringe wholly whitish; the basal third of the antemnae blackish brown, the basal half of each joint flecked on the inner side with white scales, the coloring being broadest at the base, while a few white scales are scattered over the entire upper surface which, beyoud the basal third, is dark brownish luteons; beneath, the antennae are clearlnteous, excepting the last three or four joints of the club which are uniform brown throughout; tips of the joints upon the club brown above.

Wings above moderately dark mouse-brown, uniform on all the wings, excepting that the dark markings of the onter margin of the under surface of the hind wings are more or less repeated above in blackish brown clouds, especially in the interspaces beyond the cell, and that there is a denser flecking of the dark scales on the npper half of the outer margin of the fore wings, giving a slightly darker tone at this point; fringe concolorous, but made up of mingled lighter and darker brown scales and hairs. Under surface gray brown with an olivaceons tint, arising from a dense and uniform clothing of delicate olivaceous hairs; the surface more or less faintly and very minutely mottled and showing faintly traced upon the surface three flne, brown, transverse threads, subparallel to each other and the outer border; the middle one crosses the wing, bent at the main subcostal nervure a little beyond the outer limit of the cell so as to cut off, at the base of the outer median interspace, a rhomboidal plece of equal sides; the outer thread is obscure in the npper half of the wing, and in the lower half runs a little nearer the border than the mesial line, while the imer is at a slighty greater clistance within the mesial line; these markings exist, or at least the inner pair, in a still wore obscure or modified form upon the hind wings. bat the principal markings of these consist of a large, oval, variegated patch at the margin of the wing, ahmost eutirely within the subcostal and median interspaces, the ground of which is a cinnamon brown, heavily flecked with white scales and white hairs in place of olivaceous ones; but in addition there is in the middle of all the interspaces, excepting the lower half of the medio-submedian, a marginal series of short, thick, often confluent, longitudinal, minute patches of brilliant silvery nacreous scales, those in the upper median and sub-costo-median interspaces lying confluent at the onter edge of a transverse, long oral, velvety black spot, edged narrowly with yellow scales and cut by yellow nervures into four subequal spots, to the centre of each of which a tongue of nacreons scales extends; at the upper immer border of this large variegated patch the cinnanon brown of the gronnd becomes conspicuons, since liere is the point where it mites with the transverse mesial stripe which, influenced by this patch, is here deflected somewhat from its course to form an arching margin to it. Expanse of wings, $34-38 \mathrm{~mm}$.

The following descriptions of the early stages by Edwards are given nearly in his own words :-

Egg. Subglobular, as high as broad, the base flattenerl; surface under a low power smooth, but under a high one seen to be reticulated thronglont in irregnlar hexagons, the sides of which have broad flanks that occupy nearly all the interior,
leaving but a light point in centre of each; color yellow green. Duration of this stage from three to six days, according to the temperature.

Caterpillar. First stage. Head subpyriform, one-half broader than succeeding segment, broader than high, flattened frontally, and with a slight angular depression at summit; on each vertex a straight, round, divergent horm, thick at base, pointed at top; the horn when magnified is seen to be in three sections, each smaller than the one below it, giving out at the end one or two bristles; color of head and horns blackish brown. Body cylindrical, a little thickest in middle, tapering slightly both ways from fourth abdominal segment, and ending in two divergent tails, each of which is thick at base and ronnd, tapers to a blunt point, which emits a white bristle; color of body white ; over the surface scattering white hairs. In a few days, and during this stage, the color changes to whitish green, and stripes appear, green and white alternating from dorsum to feet. Length, 3 mm . Duration of this stage in August six days, in October nine, in April six.

Second stage. Head subpyriform, truncated, higher and narrower in proportion than before, the horns longer, more tapering, less divergent, slightly curved forward, about as long as the face; the space between them not angular, but concave; color of head and horns brown, pale on front face, and green tinted; from base of each born a dark stripe passes lown the side of the face, and there is a second such stripe in front. Body nearly the same shape as before, somewhat thicker in middle, the dorsum more arched; the tails longer, more slender, and brown tipped; each segment five times creased, and on the ridges so caused a row of white tubercles, irregular, conical, each with a short white hair; color dark green, marked longitudinally by white; on middorsum a clear green stripe, and the ground on either sicle of it is whitish, owing to the nomerous tubercles there; on the verge of the dorsal area a white stripe, another along base of body, and between these, on side, are two contignous white lines; under side bluish green; feet and legs green. Length, 4.6 mm . Duration of this stage, in August five days, in October ten, in May seven.

Third stuge. Head nearly as at second stage, the horns more divergent; color of front face deep green, the back of head dull green, the stripes and horns reddish brown. Body of nearly the same shape, the tails longer; color pale green, the stripes as before. Length, 8.6 mm . Duration of this stage, in August five days, in May eight.

Fourth stage. In autumn: same shape; color soiled white, greenish on dorsmm next head; the dorsal stripe dark, the subdorsal and basal brown. Length, 14 mm .

At four days from the monlt: color now drab on dorsum, the median and subdorsal stripes darker; sides red-brown, the two lines buff; basal stripe yellow buff; under this a broad black-brown stripe the length of the body; tails drab, reddening at tips. Length. 18.3 mm .

Last stage. Nead subpyriform, truncated, on each vertex a long, conical, pointed horn, but little divergent, the space between the two at base concave; color drab, both back and face; horns drab behind, black-brown in front and between; a broad black-brown stripe down the front face, and a narrow one on sicle from base of horn. Body slender, the clorsum slightly arched; ending in two long, conical, sharp-pointed tails, which meet at base; the whole surface finely and sharply tuberculated, most of the tubercles giving out a short white hair; color buff and reddish gray in bands and stripes; a narrow gray mid-clorsal stripe, then a broad buff band to verge of dorsal area, and edged by a reddish line; next a broad gray lateral band, with a narrow buff stripe below; the basal stripe yellow-buff; beneath this a partly obsolete blackish band; tails drab, red at tips; feet and legs brown. Length, 24.4 mm . In August, ten days from third moult to chrysalis.

The same in May, from eggs laid in April. Head sordid greenish white, front and back, the stripes brown, horns red-brown; color of body light yellow-green, the dorsal stripe darker, the subdorsal and lateral lines and basal stripe yellow; tails pinktipped. From third monlt to pnpation five and six days. All the larvae, ten in number, of this April and May brood were green.
Chrysalis. Cylindrical, abdomen conical; head case scarcely produced beyond
mesonotum, narrow, excavated at sides, ending in two sharp, divergent projections, the depression between angular; mesonotum prominent, carinated, angular, the summit rounded; followed by a shallow depression; wing eases flaring on dorsal side; color of abdomen and dorsum from butt larva sordid yellow-butf, the wing and antennae cases and the projections all more sellow; the surface finely streaked brown, irregularly and mostly longitudinally; from posterior base of mesonotum to ninth abdominal segment a brown band; the wing case shows an irregular, wavy, brown stripe on disk, and a stripe on costal margin; each nervule ending in a blackish dot. Length, 11.7-13.25 mm. ; greatest breadth on abdomen, 3.6 mm .

From green larvac green chrysalids; blne-tinted, the dorsum and abdomen streaked with whitish; wing cases without stripe; the dorsal edges of wing cases carmine, and top of head case cream color. Duration of this stage, in May, eight days.

The butterfly is fomed throughout the southern states, from the sonthern part of West Virginia and Illinois to Florida and Texas, and extends also into Mexico (Monterey, Aaron) and Guatemala (Polochie valley, Butler) . It scems to be restricted to the vicinity of running water, so that though the caterpillars seem to feed readily on almost any grasses, their natural food is probably some species found only near streams.

According to Edwards it is triple brooded in West Virginia, flying in April and May, in June and July, and from about August 20 to the end of September, the winter being passed in the caterpillar state when full grown. Eggs laid in April hatch in six days, in August in three or four days, and in October six days. According to Edwards, the caterpillar has but four stages, which are passed in from twenty-five to thirty or more days, according to the scason, and the chrysalis hangs eight days in May. The caterpillar rests with the face upon the ground, so as to throw its horns forward in a reverse position to those of the tail.

## NEONYMPHA MITCHELLII.

Neonympha mitchellii Erench, Can. cnt., xxi: 25-27 (1889).
Imago. Head covered with mingled gray, black and brown hairs, paler in a stripe behind the eyes, and on the sides of the palpi; antenna honey yellow at tip, elsewhere brown, with white patches at the base of each joint. Thorax with legs above and below uniform mouse-brown.

Wings above uniform nouse-brown without markings, excepting a slightly darker edging to the outer border of the wings, on the hind wings preceded by a slightly paler line. Bencath, the same with a grayish sutfusion cansed by a profuse flecking of clay brown seales. Fore wings traversed by four narrow, ochre-yellow stripes, the inner nearly straight, crossing the outer half of the cell, the outer just within the outer margin, the other two arcuate in opposite senses and meeting above, enclosing a very large oval space, nearly one-third the size of the wing, and including in the middle, in the median and lower subcostal interspaces, a transverse series of four or five romd or romdish ocelli, the mbdle ones largest, nearly flling the interspaces, composed of an outer rim of pale yellow scales surrounding a blackish purple spot, with a few metallic blue scales scattered throngh it. Hind wings with similar transverse stripes, the middle ones enclosing a longer oval, in which are six ocelli, situated in all the median and subcostal interspaces, larger than on the fore wings, but as there the middle ones largest, in this case three in number; especially the yellow edging is broader and the metallic flecking of the interior more distinct. Expanse of wing §, 32 mm . ; ㅇ, 36 mm .

It differs from N. arcolatns in its darker upper surface, but most markedly in the form of the extra-mesial spots and in the oval enclosure of both wiugs, the former of which are here circular or almost circular, while in areolatus they are very elongated in the direction of the interspaces.

This butterfly was first described since the publication of the first part of the present work, and nothing is known of its early stages nor of its distribution beyond that it was found in southern Michigan by Prof. J. N. Mitchell, who thinks that it occurs also in central Michigan. It was taken in dry upland meadows, and doubtless will be found over a considerable extent of territory in the near future.

## CISSIA DOUBLEDAY.

## CISSIA SOSYBIUS.

Papilio sosybius Fabr., Ent. syst., iii: 219 (1793.)

Satyrus sosybius Boisd.-LeC., Lép. Amér. sept., pl, 6i3, figs. 1-4 (1833).

Cissia sosybius Scudd., BuJl. Buff. soc. nat.
sc., ii : 245 (1875).
Neonympha sosybius Edw., Can. ent., ix: 229-231 (1875);-French, Butt. east. U. S. 240242 (1886).

Imago. Head covered with long, erect, brown and pale hairs and scales, the paler oues external to all masses; the palpi with white or yellowish white scales upon the sides, brownish black scales upon the upper surface and a heary fringe of mingled black and white scale-hairs; antemne dark brownish luteous, the joints basally anuulate or subammlate with white; the club almost entirely naked, fuivo-lnteons below, fusco-lnteous above.

The upper surface of the wings is uniform rich dark slate brown, the outer margin of all the wings marked with a black thread preceded by a more or less obscure narrow palide stripe, more distinct upon the hind wings than the fore wings, limited interiorly, especially upon the lower portion of the hind wings, by a similar black thread; basal half of the fore wings in the male heavily covered with moderately long, delieate, blackish hairs, partially concealing raised scales which broaclly border the basal half of the first median nervule aud are found to some extcnt also in the lower portion of the cell.

Unice surface pale slate brown rendered more or less grayish by a scattering of dull yellow scales; both wings crossed by two distinct transverse threads of brownish fuliginous, subparal!el to the onter border, slightly tremulons but nearly straight, though more or less simous in the lower half of the hind wings; the inner crosses the wing somewhat further within the apex of the cell than the other is outside of it, and the outer is a little less than midway from the imer thread to the onter border ; the outer border edged with black is preceded by a brownish fuliginons, straight line barely separated from the outer by a clay yellow thread, and preceded by a sinuous, sublmulate, but otherwise similar thread; in the belt between the last and the extramesial thread is found on both wings a series of small, distinct anuuli; these vary iu distinctuess and importance in different parts of the wings and in different individuals: on the fore wings the most important is in the lower inferior subcostal interspace and is blackish brown, nacreous-pupiled and with a pale, dirty yellow areola; the others in the interspace above and the succeeding interspaces as far as the lowest median nervule, are even at their best rarely pupiled, with a spot generally reduced to fuligiuous brown, the arcola enlarged at the expense of the interior spot and itself bordered narrowly hy brownish fuliginous; on the hind wings the ocelli are more distinct and more brilliant, the most distinct and largest being those in the lowest subcostal and lowest median interspaces, where they are a rich blackish brown with a bluish nacreous pupil
and distinct yellow areola, bounded by a narrow, brownish fuliginons annulus which just reaches the nervoles or in the lower subcostal interspace is crowded against them so as to make the whole spot sloort oval in a longitudinal clirection; the other spots. at least at their best, are always pupiled, and slightly larger than the spots of the fore wing, though rarely much more distinct; they are nsually found in all the interspaces from the upper subcostal to the medio-submedian inclusive, in the latter occupying the upper half of the interspace. Expanse of wings, $31-37 \mathrm{~mm}$.
The following descriptions of the early stages are by Edwards, the phraseology and arrangement only altered to bring it into harmony with others in the present work.

Egg. Shape nearly that of a semi-ovoin, the base being flattened and the sides at base ronded, the surface under a low power smooth, but under a higher seen to be covered with shallow, thimble-like depressions; color greenish white. Laid July 16th, on grass, the female being conflned in a bag over a tuft of grass set in a flower pot. Hatched July 20th.

Caterpillar. First stage. Head much larger than second segment, rounded, bilobed, rather broader than long, the vertices without processes, pilose, shining black. Shape of body cylindrical, but marked by five or six longiturlinal tuberculated ridges; each tubercle sending out a clubbed white hair, some of which are curved forward, others back; color white. Length, 2.3 mm . Duration of this stage six days.

Second stage. IIcad considerably broader than first thoracic segment, rounded, a little depressed at top, angular at the sides below; color green, darker than body, much covered with fine, white, pubescent tubercles; ocelli and mandibles brown. Shape of body cylindrical, thickest in the middle, tapering evenly either way, so that the first thoracic segment is of about same breadth as the eighth abdominal ; tail forked; color light green; covered with fine white tubercles, arranged in longitudinal rows, not quite regularly, each tubercle sending out a white hair; the space between the two dorsal rows is rather broader than between the rows elsewhere, presenting a clear green mediodorsal stripe; and at extreme edge of dorsum is also a green stripe, but narrower; legs, prolegs and under side green. Length, 5 mm . To moult seven days.

Third stage. llead no broader than the succeeding segment, yellow-green, shaped and marked as before. Shape of body as before, and similarly marked, the tubcreles of unerual size: the largest arranged in the longituclinal rows, but many small ones placed on the ridges cansed by the creasing of the several segments; color blue-green. Length, 9 mm . To next monlt six days.

Fourth stage. Head emerald green, shaped as before. Bocly stout, thickest in the middle, rounding somewhat dorsally; color pale green; on either side of the darker mediodorsal stripe the row of white tubercles forms quite a broad stripe, another one at edse of dorsum, and another at base, over feet. Length, 10.7 mm . To next moult five days.

Last stage. Head rounded, broader than high, bilobed, and but little depressed at the suture, somewhat flattened frontally, broader than the first, equal to the second thoracic segment; covered with yellow, conical. fine points, arranged in close vertical rows, and at the same time in transverse rows also: the ocelli black: mandibles brown. Body cylindrical, obese, thickest in the middle, rounded dorsally, and sloping slightly to the seventh abdominal segment, then rapidly to last segment, which ends in forked, divergent tails; color emerald green, much covered with flue yellow tubercles placed on the ridges caused by the creasing of the segments, and with larger tnbercles disposed in longitudinal rows; each tubercle giving out a fine and short white hair; at basc of body the stripe is more heavily tuberculated than on dorsum; on either side of a clear dark green, mediodorsal stripe is a tuberculated stripe, and another at edge of clorsum; under side, legs and prolegs, nearly same green as above. Length, 19.3 mm . Duration of this stage seven days.

Chrysalis. Cylindrical, the abdomen stonter than anterior portion; mesonotum rounded, carinated; the head case truncated, scarcely projecting beyond the mesonotum, slightly arched at top, narrow, beveled at corners; the wing cases fiaring a little on dorsal side, the neuration of wings seen distinctly; color grecn, on the abdomen
yellow-green; on either side of dorsum on abdomen is a small ridge, and on cither side of this are three black dots, placed in pairs between the mesonotum and extremity; ou either side below wing cases a brown stripe; the keel of mesonotum brown, and the wing cases are crocked along the principal nervares, and on the margin is a black lot at the end of each nervule. Length, 10 mm . ; greatest breadth, 2.5 mm . Duration of this stage thirteen days.

This butterfly inhabits the southern half of the United States, from the Atlantie Oeean to and including the Mississippi Valley. It also extends beyond our border as far as Niearagua (Butler), and occurs in the sonthern part of our middle States. It flies in eompany with Neonympha cornelins and Cissia eurytus, according to Edwards, "keeping within the edge of the forest, or, if in the open eountry, is always near timber." It is double brooded in West Virginia, flying in July and again in the latter part of the season. The eggs hatch in four days, the first stage of the caterpillar lasts for six days, and the others about the same, while the chrysalis hangs for thirteen days, so that the whole period from egg to butterfly is about seven weeks. How it passes the winter has not been stated.

# SUBFAMILY NYMPHALINAE. 

TRIBE APATURIDI.
CHLORIPPE BOISDUVAL.

## CHLORIPPE CELTIS.

Apatura celtis Boisd.-LeC., Lép. Amér. sept., 210-211, pl. 57, figs. 1-4 (1833);-Edw., Butt. N. A., ii, Apatura i, $10 \mathrm{pp} ., 1 \mathrm{pl}$. (1875); -French, Butt. east. U. S., 215-217 (1S86).

Doxocopa lycaon Scudd., Syst. rev. Am. butt., 9 (1872).

Apatura lycaon Ril., Traus. aead. se. St. Lonis, iii : 195-198, figs. 3-4 (1873) ; Rep. ins. Mo., vi : 137-140, figs. 39, 40 (1874).
? Apatura alicia Edw., Butt. N. Amer., i, Apatura i, $2 \mathrm{pp} ., 1 \mathrm{pl}$. (186s).
[Not Papilio lyeaon Fabricius].

Imago. Head covered above with soft, very pale brown hairs; apical joint of palpi covered with dark brown scales and hairs, the rest of palpi silvery white, the dark brown of the apical joint extending slightly upon the apical portion of the upper surface of the middle joint and also flecking slightly the inner side; antennae blackish brown, above uarrowly auulate with pale yellow; beueath, tips of the joints luteous and nearly naked throughout, excepting next the base, where it is flecked with pale yellow scales; clnb wholly luteous on all surfaces, excepting the upper portion of the basal half, which is heavily flecked with dark brown scales.

Wings above sordid or gray fulvous; on the fore wings, however, this ground color is restricted to the basal third, the rest of the wing, including all beyoud the cell, the whole of the lower median interspace and half the medio-submedian interspace, dull blackish brown; within this blackisl browu portion, the wing is crossed hy two rows of conspicuons white spots, the imner row occasionally tinged with straw yellow; the onter row consists of three large, ronndish white sjots midway between the cell and the outer border, lying in a straight line in the upper median, subcosto-median and next to the lowest subcostal interspace, accompanied by a fourth smaller white spot, often amulate with black, in the lowest subcostal interspace farther toward the mar-
gin; the lowermost of these three spots is sometimes simple, sometimes, and then smaller, enclosed in a large black spot with a tawny annulus, whioh is the normal condition of a further succeeding spot in the same line, in the lowest median interspace, only that the white is reduced to a mere pupil or is totally absent; the inner series of pallid spots is strongly sinuous, lying midway between the cell and the outer row of spots, excepting the pair in the medio-submedian interspace, which seem at first sight to belong as much to the onter as to the inner series; there are two black bars crossiug the cell, one at its outer limit, straisht and subequal, the other usually broken into wo spots beyond the middle of the cell; outer border marked by a pre-apical blackbrown line on a lighter brown ground. Hind wings with a very sinnous series of oval, black spots with a tawny areola crossing the outer half of the wing in all the interspaces between the submedian and costal nervures; the second from the top, which is largest, outside and the lowest, which is smallest. inside of the straight line in which the others fall; the basal half of the wing shows more or less obseurely the markings of the under surface thrulgh the wing, but there is sometimes added a serics of more or less obscure, pallid, triangular spots, crossing the middle of the wing in an arcuate line in the subcostal and median interspaces; outer margin marked by a pair of tolerably heavy, pre-marginal, blackish brown stripes, the onter nearly straight, the inner more or lcss crenulate; fringe of both wings pale, broadly interrupted by brown at the nervule tips.

Beneath, gray brown, clonded with dark brown, the markings of the upper surface repeated with variations. Fore tings with the cellular spots brownish orange edged with black, the extra-mesial white spots of the upper surface enlarged and margined interiorly with a clistinct, strongly sinuous, blackish brown stripe which shows the double spot of the medio-submedian interspace to belong to this series rather than to the outer; of the spots in the outer series, that in the lowest subcostal and in the two median interspaces become distinct ocelli with rare exceptions, in which the spot is velvety black with a large white pupil, excepting in the lowest median where it is a mere dot surrounded by a distinct, brown edged, yellow annulus. Hind wings traversed by a very irregular, sinuous, slender, mesial, dark brown stripe, followed outside and inside, but especially ontside, by a series of pallid lunules; while at the base of the wing, included in the cell and above it, are three or four slender, transverse bars of gray-brown, heavily margined with dark brown; the spots of the upper surface are repeated beneath as distinct ocelli, and one is added in the submedio-internal interspace opposite the tip of the abdomen ; while that in the medio-submedian interspace is frequently double internally, being enclosed by a common outer ring of dark brown; these ocelli are generally faintly pupiled with pale blue and consist of a roundish oval, longitudinal, black brown spot, narrowly encircled with yellow and this with dark brown. Expanse of wings, 48-55.
The following descriptions of the early stages are those of W. II. Edwards, altered only to conform to the system einployed in the present work :-
Egg. Color pale green; in shape nearly spherical, flattened at hase, and having eighteeu slightly prominent, vertical ribs and many fine, horizontal, equidistant striae.
Caterpillar. First stage. Head round, bilobed, twice the diameter of the second segment, black, covered with tubercles. Body whitish-green, cylindrical, thickest at first thoracic segment, tapering gradually to the last, which is slightly forked; surface covered with minute tubercles from each of which springs a short hair. Length, 2 mm .
Second stage. Head either black, or purple, or green, the mandibles and ocelli brown in case green prevails; at the vertices large, green, stag-horn processes, with three fleshy prongs at top, smaller prongs below and at base, and three along the side of the head below the homs, the tips usually purple or black. Body yellow-green, the dorsum covered by a band composed of yellow tubercles arranged in two longitudinal rows, with cross rows upon the anterior part of each segment, the remaining space on the posterior part of the segment green; along the side a crenated line, and below the spiracles a straight line, each formed of yellow tubercles; scattered tubercles over the whole upper surface; tail forked and roughly tuberculated. Length, 5 mm .

Third stage. Head brown, mottled in front with pale greer, the horns enlarged. Body yellow-green above, blne-green at sides and beneath; the bands and lines as before; the tubercles much enlarged, prominent, irregular; tail more deeply forked. Length, 6.4 mm .

Fourth stage. Not essentially different. Length, 9 mm .
Last stage. Head subquadrate, longer than broad, punctate, covered with minute tubercles, greeu, with four pale, vertical stripes upon the front; mandibles and ocelli brown; horns small, yellow-green, each furnished with two short, terminal prongs, which are tipped with brown; other small prongs about the middle of the loorns and at base, and along the top of the head, and three at sides of head. Shape of body subcylindrical, being somewhat flattened dorsally, very thick in middle, tapering regularly either way, the first thoracic segment being of about the same width as the last; the tail deeply forked; color yellow-green dorsally, the blne-green on the sides; the whole surface granulated, owing to minute tubereles on the sides and larger and irregular ones on the back; these last arranged in transverse rows, separated by deep creases, there being four rows to each segment; on either side of the dorsum a clear yellow line from head to end of tail, and between these a less distinct pale stripe, on which is set an oval yellow spot on the anterior end of each segment; of ten this stripe is wanting, and the yellow spots only appear; on the side a pale yellow wavy line aud an infrastigmatal, straight line; under side and legs blue-green. Length, $30-33 \mathrm{~mm}$.

The hibernating larvae at matnrity differ from those described above principally in that the yellow spots of the dorsmm have disappeared and given place to a longitudiual yellow line, making three similar lines on a dark green ground, the inner edges of the two exterior lines being whitish; the color of the whole body is greenish-yellow. In both the body stouter on the anterior segments, the horns reduced in size, the prongs less prominent.

Chrysalis. Compressed laterally; the outline of the under side convex, regular ; the abrlomen prominent dorsally, mneh arched, sharply carinated, the anterior edge of each segment on the keel produced and clubbed and marked on either side by a shining black dot; the last segment terminating in a long, bifurcated pad of hooklets; the thoracic segments depressed at an angle of forty-five degrees from the end of the keel, the sides excavated in the clirection of base of wing; mesonotum angular, rounded somewhat at summit; the head case prodnced, subconic, the palpi cases prominent, pointed; color either delicate yellow-green or blue-green, fluely specked with pale yellow over the whole surface; the neuration of the wings distinct; a yellow line passes along the keel and to the mesonotum, at which it forks to the palpi cases; another passes along the posterior edge of the wing case, and is joined by an undulating line upon the side of the abdomen. Length, 21.6 mm .

This is a common butterfly of the southern half of the United States east of the Great Plains. It is not known to extend into Mexico.
"Celtis is exceedingly alert, restless, and inquisitive, active on the wing, but without sustained flight, and darts from one object to :unother so swiftly that the eye can scarecly follow it, alighting but for an instant on tree trunk or leaf, the dress of one passing, or the traveller's horse. More than once it has sprung upon the net which I was carrying. Its usual attitude is expressive of its disposition, the wings erect, the head and antennae raised, suspicious of surprises. But it will haunt a favorite spot for days, and the collector has only to wait patiently a while and it may be eaptured. It is readily attracted also by a sugared bait, and a string of dried apples, saturated with syrup and suspended among the branches of the tree which it frequents, may be employed to advantage. Occasionally, I have seen it
upon flowers, but a rotten apple or fallen grape is much more to its taste, and espeeially, if there is any decaying or fetid animal matter in the vicinity, it will greedily settle upon it, and then loses all sense of danger and may be covered by the net without even attempting to rise." (Edwards.)

Riley says the butterflies appear in eastern Missouri by the middle of June and a second brood of butterflies during August, but that "they overlap each other so that a few of the later individuals of the first coexist with the earlier individuals of the second, and the butterflies may be found more or less abondantly frous early June till Septembee:" Edwards says that in West Virginia some individuals hibernate, lay their eggs early in the spring and that these produce butterflies by the middle of June and that there is a second brood; but that the wintering eaterpillars begin to feed early in May and produce their butterflies about the end of May.
The eggs "are attached rather slightly to the under side of a leaf, either singly or in small clusters not exceeding a dozen. In form they are nearly globular, with very delicate, longitudinal ribs and still finer transverse striae. In hatching, the enclosed larva pushes open the crown, which lifts like a cap. When first hatehed, this larva is of a uniform yellow, sparsely covered with a few short hairs, and with a head which is jet-black and always hornless-thus differing materially from the head subserquently worn. The larvae of this, the first, brood feed for rather less than a month, when they transform and give out the second brood of butterflies during August. These lay eggs again, which in due time hatch. But the second brood of larvae thus hatehing, instead of feeding with good appetite as did the first brood, is more lethargic from the start, and develops more slowly. Every worm, after passing through the second or third molt, ceases to eat ; then shrinks in size and stations itself on the under side of a leaf. Here it changes its fresh green color for a dingy grayish brown (eaused by more or less distinct purplish marks on a dingy yellow ground), the better to keep in conformity with that of its dying support, with which, eventually, it falls to the earth, and there hibernates. A heavy snow may cover it many inches deep; a drenching rain may soak it throngh and through ; the mercury may sink $22^{\circ} \mathrm{F}$. below, or rise $80^{\circ}$ above zero; but this little worm is indifferent to all, and sleeps a profound torpid sleep from the first of October till vegetation starts anew the ensuing spring. The weather in St. Louis is often delightfully mild and even warm long after this larva has gone into winter quarters, but nothing short of the animating breath of the vernal year prompts it to renew the activity it lost the fall before." (Riley.)

In Mr. Edwards's opinion it is more probable that the caterpillar hibernates "hidden among the corky ridges of the bark of the tree."
The caterpillar feeds, like its congener, on Celtis occidentalis. "This larva is found when at rest on the under side of the leaf usually on
a carpet of silk, and often with a portion of the leaf bent around it. The lower part of the head is then drawn under the neck and the antlers thrown forward. In preparing for the chrysalis state, it spins on the under side of a leaf a little bunch of silk in which to entangle its anal prolegs. Sometimes, but not often, it partially covers itself with a curled leaf, or with two leaves drawn together. Here it rests for about two days, when the larval head and skin split open, and the soft and unformed chrysalis works them back to the extremity of its body. It then secures itself, knocks off the shrunken skin, and soon assumes the delicate green color marked with cream-yellow, and the elegant form which Nature has imposed upon it." (Riley.)

According to Edwards, the egg-state lasts in West Virginia three days, the successive larval stages three or four days each, or a total of twenty days for larval life, the chrysalis seven or eight days; so that all the changes from egg to imago are passed within a full month.
"Before the fourth moult the larva covers the surface of the leaf about its resting place with silk, and after the moult remains quiet for nearly two days, when it becomes active and feeds ravenously: the body now grows rapidly, lengthening about one-tenth inch daily, till it reaches maturity, five days after the fourth moult.
"Several of the larvae of the first summer hrood raised by me, in 1873 , stopped feeding after the second monlt, and commenced their hibermation. Some composed themselves on the leaves in the glass in which they were kept, others directly on the sand at the bottom of the glass, in either case upon a coating of silk. The color of these larvae soon changed to brown, in which was to be seen, under the microscope, a mottling of vinous and green. The last fall brood all assume this color, and hibernate also after the second moult. And the earlier broods sometimes all hibernate, as I observed last scason (1874)." (Edwards.)

Limmeria fugitiva has been fomd attacking this insect by W. H. Edwards in West Virginia.

## ANAEA HÜBNER.

Anaea Hübn., Verz. bek. schmett., 48 (1816);- (1875);-Kirb., Cat. diuru. Lep., 276 (1871).
Scudd., Proc. Amer. nead. sc., x:111 Paphia pars Auctorum. (Nom. pracoce.)
Imago. Ifead small, compact, closely appressed to the thorax. Front scarcely at all tumid, with rigidly straight sides, as broad only as the face view of one of the eyes and much higher than broad. Eyes moderately large, not very full, naked. Antennae separated at base by the width of the basal joint, their exterior bases close upon the margin of the eye; longer than the abcomen, straight, composed of about 37 joints, the club of about thirteen joints, but slightly larger than the stalk, which itself en. larges faintly from base to club; the latter terminates in a bluntly rounded apex, composed of four excessively short, naked joints which radiate outward and are together scarcely larger than one of the ordinary joints of the club. Palpi very compact, the
clothing compact, the inferior fringe double with a deep longitudinal carina between, fading out apically; the minute apical joint scarcely longer than the width of the equal, basally curving, sleuder second joint, the apparent size of which is donbled by its dense clothing.

Fore wings pretty strongly falcate, the costal margin with a strongly descenting apical curve, the apex finely pointed. Cell hardly more than two-ffifths as long as the wing, closed, the closing vein slight, with no recurrent nervule, largest in the middle, only slightly narrowed beyoud, three times as loug as broad; subcostal nervure with ouly two superior branches, the second arisiug far toward the apex; flrst inferior nervule originating before the apex of the cell. Hind wings with both onter and anal angles prominent, the former rounded, the latter rectangular, the upper median nervule prodnced to a distinct, equal tail. Cell closed by a barely perceptible thread, enlarging slightly just next the subcostal, which it strikes opposite a point midway between the two divarications of the median nervure.

All the legs short and stout. Fore legs clothed alike in both sexes, like the femora of the other legs, the tibiae of the male half as long as the hind tibiae, the tarsi half as long as the tibia, composed of a single, bluntly pointed joint. Other tarsi abont as long as the tibiae, the first joint equalling the next three in length, the ffth longer than the second, all densely scaled above and beneath and furnished also beneath with four rows of rather stont, obliquely set, not closely crowded spines, the apical ones of each joint no larger than the others. Claws slender, strongly curred and finely pointed, the paronychia scarcely shorter than the claws, exceedingly slender and thread like.

Egg. Nearly spherical, a little higher than broad, somewhat flattened at base and slightly depressed at top, with a few parallel horizontal series of raised points encircling the shoulder of the egg (after Edwards).

Caterpillar at birth. Ifead rounded at summit. Body eylindrical, tapering from in front backward, with four longitudinal series of large tubercles, each supporting a hair, three of the rows above, the fourth below the spiracles on each side (after Edwards).

Mature caterpillar. Head well rounded on a front view, somewhat profusely covered with papilliform gramulations, of which three or four larger ones are clustered at the top of each hemisphere. Body cylindrical, the anterior part of first thoracic segment strangulated; otherwise nearly equal in anterior half of body, tapering posteriorly, the last segment entire and rounded posteriorly; whole body peppered with subequal granulations, very bluntly rounded at tip, bearing an exceedingly brief hair; segments obscurely divided into a large anterior section occupying more than half the segment and two smaller, subequal posterior sections. Legs stout at base, slender and short bejond; prolegs short and stout.
Chrysalis. Very short and stont, broader than high, transrersely ridged above the wings in the middle of the abdomen, the ridge extending from the anterior limit of the fourth abdominal segment, at the sides, to the middle of the same on the dorsum; laterally carinate from the front edge of the lower surface backward over the basal wing tubercles, nearly but not quite to the hinder edge of the wings; behind the abdominal ridge, the abdomen tapers with exceeding rapidity to the small cremaster. the face of the globular tip of which is in the plane of the under surface of the body; this last below the lateral carina is regularly convex, less strongly than the dorsal surface; mesonotum geutly arched, full, above on side view rounded, tectiform; body broadest at posterior margin of the wings, tapering gently and regularly forward to the basal wing tubercles, then rapilly to the narrow truncate front.

This is a tropical American type of butterfly with many species, one or two of which extend into the United States, and one passes northward to some distance up the valley of the Mississippi. Their robust form, warm upper surface, dead leaf under surface, falcate fore wings and tailed hind wings make them rather striking objects, though they show no great variety or beauty of pattern.

The transformations of several species are partially known. The caterpillars feed upon apetalous plants of allied families, Lauraceae, Piperaceae, Euphorbiaceae, and have some strangely curious habits. In the first half of their lives they live openly, devouring a single leaf from the tip baseward, when not feeding resting on the spared midrib, and leaving bits of eaten leaf strung along the midrib by silken threads. When partly grown they change their habits completely, construct a nest from a single leaf just large enough for their body, which, whether it be a living leaf or one which by detachment dries up, they always quit to feed, retiring thereto immediately thereafter. The resemblance these habits bear to those of our Basilarchia, and the divergencies of the same are particularly interesting and worthy of study. It may throw some light upon the origin of the habits of one or the other type, especially in the particular custom of attaching frass to the midrib of the eaten leaf. It is the more curious, as these insects belong to different tribes of Nymphalinae.

## ANAEA ANDRIA.

Anaea andria Scudd., Bull. Buff. soc. nat. sc., ii: 248 (1si5).
Paphia glycerium Morr., Syn. Lep. N. Amer., 67 (1862) ;-Ril., Amer. ent., ii :121-123, figs. $81-83$ (1870);-EdTr., Butt. N. Amer., $i$, I'aphia 3 pp., 1 pl. (1871).

Paphia troglodyts French, Butt. east. U.S., 226-229 (1886] ;-Edw., Can. ent., xx : 41-45 (1888).
[Not Paphia glycerium Doubl.; nor Pap. troglodyta Fabr.]

Imago. ILead covered above with vinous brown hairs ; palpi gray, delicately variegated with darker and lighter brown, pallid, dark orange and yellow scales; antennae uniformly black brown above, beneath ferruginous, heavily flecked at the base of each joint with white scales; the club luteo-ferruginons beneath, above like the stalk, with the apical joint naked, ferruginous.

Wings above either rich dark orange, margined more or less deeply and distinctly with brown ( $\delta$ ) ; or, sordid, dull, and rather pale orange, heavily margined with dark brown and with a very irregular, transverse, broad, paler band crossing both the wings, edged on either side with dark brown ( $f$ ) ; the brown edging of the wings is dark, generally not distinctly bordered on the inner side, at least in the male, and toward the outer edge covered with a bluish bloom in fresh specimens; there is a narrow, transverse bar of blackish brown at the extremity of the cell of the fore wings, much more distinct in some specimens than in others; the transverse stripe of the female fades out before reaching the inner margin below, generally stopping at the submedian nermure; above, it forks, one fork directed toward the apex of the wing, the other at right angles to the costal margin; the extra-mesial belt of the hind voings in the female is formed of two portions narrowly united at their corners, the upper occupying more than half of the apical half of the costo-subcostal Interspace, the remainder a belt broadening from above downward, fading out in the lower half of the wing; the blackish brown inner edge of this band is generally seen to a greater or less extent in the male.
Beneath uniform dry-leaf brown, more or less glaucous, the femalegenerally with a strong vinous or ferruginous tint; the markings of the upper surface merely indicated below, and the whole of the wings flecked with minute spots or transverse threads of dark brown; the male is therefore much more uniform than the female, but, as special markings, are often found a pre-marginal series of clay brown points in the interspaces of the upper half of all the wings, besides a similar clustering of clay brown
scales in the middle of the costo-subcostal interspace of the hind wings, and occasionally a similar cluster in the subcosto-median interspace, where the extra-mesial dusky band crosses it; these markings are rarely seen in the female, but may be indicated in a trifling manner. Expanse of wings, $\delta, 60-74 \mathrm{~mm} . ;$, $66-78 \mathrm{~mm}$.
The following descriptious of the early stages are borrowed from W. H. Edwards, with slight transpositions and alterations of terminology.

Egg. Nearly spherical, a little higher than broad, somewhat flattened at base and slightly depressed at top; surface smooth; crossed near the top-at about onc-fifth distance from top to base-by two to four parallel rows of raised points, about twentytwo in the full circle; these seem to be placed in vertical lines; in some examples the rows are nearer together than in others, and there is often irregularity in the number or position of the points, some of the series wanting, or misplaced, in this last case lying between the rows. Color pale green.

Caterpillar. First stage. Ilead a little broader than first thoracic segment, rounded at top, outline that of a borseshoe, the front somewhat fiattened; color yellowish; across the forehead a broad stripe of brown, within which are two little patches of the yellow ground, one on each lobe, and the stripe bends at right angles, and narrowing passes down each cheek; in a curve about the top in front, six small tubercles, and near the sutures two others, which with the second and fifth of the curred row make a cross row of four. Body cylindrical, tapering from first thoracic to niuth abdominal segment on dorsum and sides, the end of the ninth segment rounded; color brown green; the cross ridges on each segment studded with small, white, rounded tubercles, from the top of each coming a short, fine, white hair; there are also four rows on either side of large white tubercles, one to a segment, three above the spiracles, and one below the spiracles, each with a short, stiff hair ; each of the basal row has a half circle of small tubercles, but larger than those over the dorsum on its lower side; under side, legs and prolegs nearly as abore, a shade more green; the first, second, seventh and eighth abdominal segments are crossed by two or three rows of tubercles. Duration of this stage three to five days. Lengtl, 2.3 mm .

Second stage. Head higher than broad, narrowing at upper part, depressed at suture; color of upper front greenish; over mandibles yellow white, at the back gray green; on each vertex a low, duplex, black process, the outer part larger and higher than the other, each with a black, short bristle at top; at back, on either side the suture, a duplex, small. yellow process, and others down the side of face at back; over the front minute tubercles as at first stage, and in addition three large, conical, white tubercles on either lobe, each three in triangle with base above, so arranged that four tubercles cross the forehead in line. Shape of body as before; color gray green; the dorsum of eighth and ninth abdominal segments discolored brown or blackish, aud a subdorsal patch of same hue on the fourth and sixth segments; thickly covered with fine tubercles as at first stage; the rows of larger tubercles as before, ivory white, bell-shaped, the hair or process from top brown or black; the basal tubercles large, each with its crescent of smaller ones, on lower side. Length, 4.6 mm .

Third stage. Head shaped as before; the processes on vertex larger, triplex, shining black, two being in line across front, the outer one larger, the third lying behind and between the others; the back and the front face armed as before. Shape of body as before; tuberculated as before; color gray brown, discolored on posterior segments as before. Length, 6.3 mm .

Fourth stage. Head as at last previous stage, the front greenish black, the vertex processes black; of the four cones across front the outside ones were black, the others white with brown rings at base. Shape, armature and color of body as before; there is much variation in the extent of the black; on one example the second and seventh abdominal segments were quite black dorsally, on sides of the fourth and fifth ten black patches, on sides of the second and third thoracic and first abdominal segments paler black; another was pale black on the eighth and ninth abdominal segments, a very little of same on the flrst and second, and the sides of the fourth to sisth abdominal segments pale black. Length, 8.6 mm .

Last stage. Head subovate, depressed at top, the heigbt to the breadth as eight to seven; color gray green, thickly covered with tubercles like those on body, small and large; among these are larger ones, three on either lobe in triangle, so disposed as to make a row of four across the forehead; these are white, with a browu rim about base, or the inuer pair are white, the others black; on each vertex a triplex process as deseribed at fourth stage, black; along the back and sides white processes, of which a duplex or bifid one, taller than elsewhere, stands on either suture; ocelli black. Body stout anteriorly, thickest at the second and third thoracic segments, tapering on dorsnm and sides to the ninth abdominal segment, the end of the latter rounded and the dorsum much curved; color gray green, the first thoracic segment darker green; usually marked by patches of black on dorsum or sides of segments, after the second abdominal segment, bnt some examples have little, or it is pale colored, and others have none at all; eutire upper surface studded with low, rounded tubercles, varying in size, bnt always small, placed on the cross ridges; these are whiter than the ground color, and from each proceeds a very short, straight white hair; under side, legs and prolegs a shade lighter than the upper; the first, second, seventh and eighth abdominal segments erossed by tubercles. Length, 33 mm . Freneh gives the length of mature larva as 39 mm ., and probably wild examples are larger thau my bred ones.
Chrysalis. Shape much as in Anosia plexippus, the last segments retracted in the same way, so that the abdomen is greatly shortened, and the shape that of a dome; the head case short, narrow at top, and beveled to a sharp, slightly iuenrved ridge, the sides sloping, mesonotnm prominent, carinated, rising posteriorly to a rounded point, the slope to top of head regular, and at about $45^{\circ}$; the depression behind shallow and broad; the dorsal edges of wing cases prominent; the sides excavated; color light green, granulated with whitish; the edges of wing case and top of head case whitish. Length, 16.5 mm . ; breadth at mesonotnm, 9.7 mm ; at abdomen, 10.2 mm .

The Mississippi Valley is the home of this butterfly, where it extends westward to the Great Plains, but not far to the eastward, and from southern Illinois to the Gulf. It is shy and difficult of capture, its flight exccedingly rapid "with a dry, whistling sound. Although easily alarmed, it seldom leaves a favorite locality, but continues to fly about until danger has passed. It is curious as the Vanessas, and I have several times taken it by standing motionless, when after numberless rapid circlings and dashes about me, it would suddenly alight on the ring of my net." (Edwards.)

Until recently our knowledge of the life history of this butterfly was due principally to the field observations of Mr. Nuhleman and Dr. Hayhurst, both of whom were satisficd that there is but a single brood annually, which appears at the very end of the season at end of September and October, and goes into hibernation carly in November. Dr. Hayhurst remarks "the food plant docs not sprout up and leaf sufficiently to support the larva before 1st of July." But latterly Mr. Rowley, who furnished Mr. Edwards with the material for his fuller study of the early stages, asscrts that there are at least two broods of the imago, and that there is a deeided seasonal dimorphism in the two broods of the female.

The larva feeds on an annual, Croton capitatum, one of the Euphorbiaceae, which is tolcrably common in Illinois, Missonri, Kentucky, and westward, where it is known by the name of goat-weed (Riley), and also on C. monanthogynum, as the butterfly is to be found where the first plant
dues not grow but the latter does (French). Mr. Rowley has found them on bath.

The eggs are usually laid singly on the under side of the leaf, and hateh in four or five days. "The young larva, soon after emerging, constructs for itself a perch on which it rests, after the manner of a [Basilarchia]. It is at the tip of the leaf, made by eating away along-side the mil-rib, and using this rib as the basc, eovering with silk and lengthening by chewed bits of leaf bound and held by the silk. One perch in first stage measured [ 7 mm .] in length, and on it the larva rested with the anterior segments arehed, only the prolegs furnishing the support. But if there be two larvae on one leaf, the second pereh may be made anywhere at the side. After the first moult the pereh was lengthened and made heavier by binding it with larger pellets, so that it looked like a string of knobs, and the greatest length I observed was [ 10 mm .]. The young larva bears much resemblanee in body and head to young [Basilarehia archippus], but is more like that larva at second stage than the first, and the head with its many tubereles and processes on vertices and at back still mure resembles either second or third stage of [arehippus] than the first.
"After the second moult, the pereh is deserted, and a ease is made by covering the upper surface of the leaf with silk, and bringing the edges together. The larva lies at first quite concealed, and eats the base of the leaf. Here the next moult takes place, and the larva then builds a new case, and goes ontside to feed, after the habit of the nearly mature [Euphocades] troilus. By the time the fuuth moult approaches, the larra is as long as the ease, and the head will be exposed at one end, and tail at the other, the rounded ease being a pretty good fit, rather loose." (Edwards.)

The goat-weed "has a peculiar wooly or hairy, whitish green appearance," says Riley, in his carlier account, "and in the month of September its leaves may frequently be found rolled up, with the larva inside. This roll of the leaf is generally quite uniform, and is made in the following manner : Extending itself on the midvein, with its head towards the base of the leaf, the larva attaches a thread to the edge, at about one-fourth the distance from the base to the point. By a tension on this thread, it draws this edge partly toward the opposite one, and fastens it there, being assisted in the operation by the natural tendency of the leaf to curl its edges inward. Fastening a thread here, it repeats the operation until the edges meet, and then it proceeds to firmly join them nearly to the apex, leaving a small aperture through which to pass the exerement. During hot days the larva remains concealed in the leaf, and towards evening comes out to feed, though sometimes it feeds upon its house, eating the leaf down halfiway from base to point. It then abandons it and rolls up a new one. In the breeding eage, when placed in a cool, shady room, the larva seldom rolls up the leaves, but feeds at random over the plant, and when at rest simply remains
extended on a leaf. From this we may infer that its object in rolling the leaves is to shield itself from the rays of the hot August and September sun, for the plant invariably grows on high, maked prairies." (Amer. ent., ii : 121-122.)
"During the heat of the day it remains concealed, but towards evening comes out to feed, though sometimes it feeds upon its own house, eating the leaf halfway down from base to point, then abandoning it and rolling up a new one. When placed in a cool, shaded room, the larvae seldom rolled up leaves, but fed at random over the plant, and when at rest simply lay extended on the leaves. Many, though not all, of the rolled leaves that I cut open, were completely lined with a closely woven coating of strong, white silk. . . When ready to transform, it spins a button of white silk on the under side of a leaf or branch, and, fastening the anal legs therein, doubles upon itself until the extremities meet. In this position it remains about twenty-four hours, when it suddenly throws off its larval skin and becomes a chrysalis. Some of my chrysalids were eighteen and twenty days before the butterfly emerged." (Edwards, Butt. N. A.)

The insect lives neally a month in the caterpillar stage, the chrysalis state appears to vary from nine to twenty days, and according to Rowley the pupa is often found attached to a branch of the food plant.

# TRIBE ARGYNNIDI. 

## SEMNOPSYCHE SCUDDER.

Semnopsyche Scudd., Bull. Buff. soc. nat. sc., ii: $2 \overline{5} 8$ (1875). Argynnis pars Auctorum.

Imago. Head large. Front more protuberant than in Speyeria but otherwise much as there, as is also the vertex, which is slightly less developed. Eyes very large and prominent, naked. Antennae inserted in deep pits, separated by the width of the third joint, considerably louger than the abdomen, composed of fifty-four joints, of which twelve or thirteen form the club, which is depressed cylindrical, fusiform-oval, a little more thau twice as long as broad, nearly four times as broad as the stalk, the apex roundcd, but the extreme tip produced to a point by the last joint; the broadest joint in the middle is about five times as broad as loug and the longest joint of the stalk about three times longer than broad. Palpi moderate with a heavy, moderately brief and close, inferior fringe; joints much as in Speyeria.

Fore wings ample, the costal margin arched more even than in Speyeria, the apex very regularly rounded, the outer margin distinctly though slightly excised in the male. Second inferior subcostal nervule arising from the first inferior (where it forms the upper half of the closure of the cell) at its extreme base, without leaving a short pedicel before it as in Argynnis and Speyeria; last median nerrule not so conspicuously arcuate as in Speyeria. Hind wings with the oblique excision of the aual angle more pronounced than in Speyeria by the considerable shortening of the internal nervure. The neuration otherwise much as in Speyeria, but with less abruptly bent curves.

Fore legs slender, the tibia about two-fifths the length of the hind tibia, the tarsi of the male consisting of a long, tapering member as long as the tibia aud with two brief joints faintly marked off at the apex. Hind tarsi considerably longer than the tibiae,
the first joint as long as the next three together, the fifth equal to the third. Claws as in Speyeria but stouter; paronychia very slight, slender, closely appressed to the claw, not half its leugth, curviug iu au opposite direction, thread-like; pulrillus small, circular, on a long pedicel.
Egg. Closely resembling that of Speyeria, from which it apparently differs in the more numerous horizontal raised cross lines, making the quadrangular cel!s relatively broader than in Speyeria.
Mature caterpillar. To judge from Mr. Edwards's description, the only material at hand, the caterpillar agrees with that of Argynnis rather than that of Speyeria and is remarkable for the length of the laterodorsal spiues of the first thoracic segment.

Chrysalis. This again agrees better with Argynuis than with Speyeria but I bave no specimens for a proper study of its relations.

This genus comprises but the single species here described, to which reference is made for further details.

## SEMNOPSYCHE DIANA.

Papilio diana Cram., Pap. exot., ii : 4, pl. 98, figs. D, E (1779).
Argynnis diana Say, Amer. ent., pl. 71
(1824); Proc. ent. soc. Phil., iii: $431-133$
(1564);-Edw., Butt. N. Amer., i, Argynnis 1
(1868) ; li, Argynnis 7 (1876); Can. ent., vi: 121-124 (1874) ;-French, Butt. east. U. S., 153155 (1886).

Semnopsyche diana Scudd., Bull. Buff. soc. nat. sc., 1i: 259.

Imago. Head covered above with fulrous ( $\delta$ ) or black mingled with a few fulvous ( $¢$ ) hairs; palpi fulvous with black hairs; antennae blackish fulvous above, fulvous beneath; the club excepting the extreme base and tip black.
Wings above black brown with a nearly uniform, purplish tiuge on the basal threefifths; beyond this the two sexes differ completely: In the male the dark basal color rums in the fore wings in narrowing threads along the nervule tips, half or more than half way to the margin giving a strongly lunulate boundary to the basal color; the onter third of the wing, or more than that above, is bright fulvous orange aud is crossed by two series of black brown powdery spots, the inner more distinct than the outer, parallel to each other and the outer margin; the inner crosses the middle of the outer half of the wing, the outer is nearer to the outer border than to the inuer series and the black-edged margin is preceded by a powdery thread of blackish brown enlarging into spots at the nervules. On the hind wings the dark basal portion is separated from the outer orange fulvous portion by a nearly uniform, arcuate line subparallel to the outer border, lunulate only in the subcostal interspace where, as also in the median interspaces, just outside the dark bordering, is a minute, powdery, blackish brown spot; extreme margin as in the fore wings.

In the female the black purplish color of the base is extended over the entire fore woing, but it includes in the outer half three series of bluish white powdery spots, the outer series and the middle spots of the middle series more solid; these three series run parallel to the outer margin; the outer and inner series consist of roundish spots, the middle of longitudinal bars, and these occur in nearly every interspace in the wing; and besides them there are three powdery dashes, the lowest inconspicuous, depending from the costal border within the inner series of spots. On the hind wings the color of the base is also extended to the margin but is deeper in tint excepting where it is traversed by the markings; these consist of a very brown, parplish blue, extra-mesial band broadly severed by the nervures, the inner limit of which is similar to the inner limit of the orange exterior of the female, distinct and black-edged; the onter is powdery and vague, terminating at about an interspace's width from the onter margin, and within this band, next its inner margin, is an arcuate series of five, large, round, blackish spots in the subcostal, subcosto-median and median inter-
spaces; there is a pre-marginal series of transverse, equal, purplish blue bars more or less flecked with white in the interior, forming a disconnected stripe.

Beneath, the color of the two sexes differs as much as above: In the male, the fore wings have much the general color of the upper surface but less pure in tone and excepting also that the basal half of the wing is mucl variegated by a series of tawny, transverse bars in the cell, the outer next its extremity, very largely powdery with silvery white scales, and a transverse, arcuate, mesial series of fulvous, longitudinal, quadrate or triaugular bars a little beyond the extremity of the cell. Hind wings buff, paler in the onter than iu the inner half, the latter being more or less ferruginons, the two parts separated by a broken blackish thread; there is also a transverse blackish thread crossing the npper half of the wing next the second divarication of the subcostal nervure, accompanied in the costo-subcostal interspace, as is also the outer thread, by a number of silvery white scales, a few of which are also sometimes found in the cell and at the extreme base of the costo-subcostal interspace; a pre-marginal series of flat, silvery lumules margined outside and to some extent inside witl black scales.

In the female the color of the fore vings is that of the upper surface, excepting that it is paler and less bluish in tone externally; the extra-mesial series of spots is much as above but intensified and is preceded in all the interspaces by long and large, quadrangular or triangular, powdered patches of blue scales which are also found marking irregular, transverse bars in the cell; the other outer markings of the upper surface of the wing are scarcely repeated beneath, excepting in faint indications. Hind wings dingy chocolate brown at base, bluish brown beyond, limited by a faint, interrupted series of dark blue, slender, transverse bars, marking the same position as the limits of the two colors above; the silvery markings of the male are repeated vaguely and generally with more of a decided bluish tinge. Expanse of wings, male, 94 mm ., female, 104 mm .

Egg. Conoidal, truncated, depressed at summit, marked vertically by about eighteen prominent, slightly wavy ribs, eight of which extend from base to summit, and form around the latter a serrated rim or crown ; the remainder lie between these and end irregularly at one-balf to three-quarters distance from base, sometimes squarely at one of the transverse striae, but often curve towards and unite with the long ribs; between each pair of ribs are equi-distant, transverse striae, about twelve in all, each one depressed in the middle and not often in line with the corresponding striae of the adjoining sections; the spaces between the ribs and striae excarated ronndly. Height, 2.2 mm . ; breadth at base, 2.3 mm . ; at summit, .85 mm . [The measurements are surely much too great.]

Caterpillar. First stage. Head rounded in front and at the vertices, depressed in middle at top; color blackish brown, sparsely pilose. Body cylindrical, thickest at first and second abdominal segments, tapering slightly toward either extremity; color dull green, translucent; each segment from second thoracic to seventh abdominal marked by a transverse row of eight elongated, mostly obovate, tubercular, clark spots, the second on either side the dorsal line lying back of the rest; on the eighth abdominal segment a straight row of four spots, and behind this another of two spots; the first thoracic segment is narrow and is occupied dorsally by a blackish, oblong patch, on the front of which are four small, rounded tubercles, and immediately behind each of the two outer ones a similar tubercle; in addition to these, on either side of this segment are two spots like those upon the other segments; from each of the tubercular spots throughout spring one or two long black hairs, curved forward. Length, 2 mm .

Second stoge. Head black. Body same shape as before; color olivaceous, mottled over the whole surface with brown; armed with six longitudinal rows of long, fleshy, black spines, each of which springs from a yellowish tubercle; these spines are somewhat tinted with fulvous at base, and from the sides and end of each proceed short, curved, black hairs; legs and prolegs dull green. Length, 3.8 mm .

Thirl staye. Front of head blackish brown, bristling with hairs; back of head, at the junction with segment behind, dull yellow. The segments from third thoracic to
seventh abdominal enlarged, on thoracic segments tapering forward more rapidly than before; color uniform obscure greenish brown; the spines as in the last stage, a dull yellow tubercle forming the base of each; legs black, prolegs dull green. Lengtl, 7.6 mm .

Fourth stage. Head sub-conic, truncated, with a prominent vertex on either side, between which and the apex is a rounded depression, the front flattened, the lower angles rounted; color brown in front, dull yellow behind; the ocelli black. Color of body as in last stage, the upper surface with a silky gloss; the spines longer and more tapering, the basal third of each and the tubercle also orange; the bristles shorter; legs and prolegs black. Length, 17.8 mm .

Fifth staye. Head black. Color of body miform deep chocolate brown; the spines as before, except those of the two dorsal rows on first thoracic and last four abdominal segments, all of which are black; the bristles shorter ; between the dorsal rows on each segment are two whitish dots. Length, 25.4 mm .

Last stage. Head small, but broader than the segment behind, sub-conic, truncated and depressed at top, flattened in front, the lower corners rounded, the vertices prominent, the surface sparsely pilose; color brown, hehind fulvous. Body eylindrical, fleshy, tapering at either exthemity, each segment roundew; wholly velvety-black; armed with six rows of long, tapering, sharp, glossy-black spines, from each of which proceed several short, black bristles on the sides and one at the top; length of most of these spines, 5 mm ; on the first thoracic segment the two dorsal spines measure 7.5 mm . and are projected forward over the head; on each side of same segment is one other spine, starting from the posterior edge of the segment and back of the line of the clorsals, and these also are porrected; the remaining spines of the six rows radiate as if from a central axis, those of the stigmatal row being depressed so that their euds are on a level with the feet; the base of each spine deep orange or fulvous: between each pair of dorsals two whitish dots placed transversely; legs and prolegs black. Length, 63.5 mm .

Chrysalis. Cylindrical, with an angular excavation below the mesonotum; the whole surface finely corrugated; head-case square, transversely rounded, with somewhat prominent vertices; mesonotum prominent, compressed, carinated, rounded at summit and with a sharp tubercle at base on either side; two other tubercles just below and back of the head; wing-cases much elerated ahove the surface, the onter edges at base flaring; on the abdomen two dorsal rows of long, sharp tubercles, and smaller ones, corresponding to the first lateral spines on the larva, on the three or four middle segments; color of the anterior portions and of the wing cases light brown, streaked with darker shades; of the abdomen dark brown mottled on the sides with red. Length, 30.5 mm .; greatest breadth, 1 l mm .

All the above descriptions of the early stages are copied from Edwards with slight transpositions and alterations of phraseology.

This butterfly appears to be an inhabitant of the hilly country of the south, following the Alleghanies, and a comparatively narrow belt westward at about the 38 th parallel of latitude. How far west it reaches is unknown. No one appears to have found it west of the Mississippi since the time of Say, who says he has taken it in Missouri and the "Arkansaw" of that day.

It is a single brooded species, the males of which fly throughout July and August and the females throughout August and September. The eggs hatch in about fifteen days, the young larvae go at once into hibernation, and in the spring the successive stages of the caterpillar, which feeds on violets, occupy more than a fortnight each, while the chrysalis hangs for three wecks.
"Both sexes are conspicuous, the males from the strong contrast of color, and the females from their great size and the habit of alighting on the topmost flowers and resting with wings erect aud motionless. It is an exceedingly alert and wary species, differing in this from our other Argynnides. At the slightest alarm it will fly high into the woods, near which, upon the narrow bottoms or river slopes it is invariably found. It is a true southern species, sensitive to cold, not to be looked for in the cooler part of the morning, but flying down from the forest when the sun is well up. From eleren to three o'clock is its feeding time" (Edwards).

There is scarcely another butterfly in the whole of North America in which the contrast between the sexes is so great as in the present species. This is the more striking since it belongs to a group remarkable for the similarity of markings in the two sexes, its next neighbor, Speyeria idalia, being the only one where an appreciable difference exists (except for the patches of androconia) and here it extends to the color only of a row of spots found in both sexes alike. This difference, as we bave pointed out in the body of this work, is a clear case of parastatic mimicry, the mimicry affecting the female only (as most in need of such protection), and is the more surprising since the butterfly mimicked belongs to the only genus in our fauna, where, in other species, parastatic mimicry of a Euploeid butterfly occurs. If a butterfly of the genus Basilarchia needs protection and gains it by mimicry of Anosia or Tasitia, why should Semnopsyche take to imitating a normal Basilarchia? That it does closcly resemble it any one can see, and the following passage from Edwards, writing of the discovery of the female, may be taken in evidence : "While breaking my way through a dense thicket of [iron-weed], hoping to find another diana [male], I came suddenly upon a large black and blue butterfly, feeding so quietly as to allow me to stand near it some seconds and watch its motions. It seemed to be a new species of Limenitis [Basilarchia], allied to ursula [astyanax], which it resembled in color."

It inay also be pointed out that its range is altogether included within that of Basilarchia astyanax.

## ARGYNNIS FABRICIUS.

## ARGYNNIS ALCESTIS.

[^2][^3]rupted stripe, composed of moderately narrow black bars or lunules in all the interspaces above the submedian nervure, at very different distances from the outer margin, the general direction of the whole band being twice bent at a right angle, at the upper median and lower median nervules; in the middle of the outer half of the wing a transverse, almost straight series of round black spots, largest in the median nervules, becoming longitudinal streaks in the uppermost subcostal interspaces; and finally, between these last and the mesial band, the subcostal nervures are marked in black and accompanied by a powdery bar, clepending from but not touching the costal margin; onter margin followed within, at the clistance of half an interspace, by a black-brown stripe connected with the margin by powdery bars at the nervules, and preceded by a series of delicately formed black lunules in all the interspaces, wholly independent of each other and enclosing between them and the pre-marginal stripe faint orange spots, which are not wholly enclosed; fringe brown, interrupted with white or luteous. Hind wings excepting for their deeper and richer tone, wholly resembling those of A. aphrodite, and excepting, also, that the interrupted bent band of the lunules found in aphrodite is replaced here by transverse bars of smaller extent.

Beneath, the fore wings do not differ from those of A. aphrodite, excepting in the markings being less heavy, nor do the markings of the hind wings differ so far as regards the position, number, relations and form of the silvery spots; but the ground color is of a nearly uniform cinnamoneous, in the outer half of the wing more or less bathed with dull fulvous orange, excepting in the near vicinity of the spots; there is, herefore, in the outer half of the wing, between the two rows of silvery spots, a narrow stripe of lighter color, as in A. aphrodite, and, as there, the color is much the same as that bordering the margin of the wing; but the contrast is here very slight between this lighter band and the parts surrounding it, so as to make it far less conspicuous. Expanse of wings, $75-77 \mathrm{~mm}$.

I give here Mr. Edwards's descriptions of the early stages, with such modifications of the phraseology as are necessary.

Egg. Conoidal, truncated, not so broad at base as in S. iclalia, the sides less rounded; depressed at summit, marked vertically by about eighteen prominent, slightly wavy ribs, balf of which extend from base to summit and form around the latter a serrated rim; the remainder end irregularly at two-thirds to three-quarters clistance from base, sometimes squarely, at one of the striae, but usually curved towards and unite with the long ribs; between earh pair of ribs are equidistant, transperse striae. Shape of A. aphrodite and B. myrina, being more slender, narrower at base, and less convex on sides than the other large species of this genus. In Mrs. Peart's magniffed drawings the eggs of A. alcestis and B. myrina are indistinguishable from each other.

Caterpillar. First stage. Head a little broader than any segment, rounded, slightly bilobed, somewhat pilose, color dark brown. Body cylindrical, thickest anteriorly, tapering backward, the dorsum sloping considerably; color brownish green, translucent; each segment, from the second thoracic to the eighth abdominal, marked by eight rows of tubercular dark spots, six of them placed on dorsum and upper part of sides, each spot giving out a long, black, clubbed hair, which is curved forward; the other two rows are beneath spiracles (one on each side), and consist of much smaller spots, each with two or three short hairs; still lower down, in a line orer the legs, are points with fine hairs; on the first thoracic segment is a blackish dorsal patch, and on either side are two small spots, and all these are furnished with hairs; on the ninth abdominal segment is a row of four small spots, and behind it one of two. Length, 2 mm .

Second stage. Head subcordate, black, with many short, black hairs. Body thickest in middle; color yellow green, on dorsum mottled with brown, especially at bases of spines; six longitudinal rows of large spines, besides a row of very small spines along base of body, over the feet; the laterodorsal series begins at the first thoracic and runs to the niuth abdominal segment, one upon each segment; the two rows on the sides begin at the first abdominal segment, and of these the laterostigmatal series stops at the eighth abdominal segment, the lower continuing to the next, always but one on
each segment; on either side of the first thoracic segment are two minute tubercles with hairs, two also on the middle, and three on the last thoracic segment; between each of the thoracic segments, at the junction of the segmeuts, is set a large spine, which lies betreen the laterodorsal spine and the next higher spine on each side; spines long, tapering, black, beset with many short and fine, black bristles; the spines on infrastigmatal row now rise from yellowish tubercles (but in some examples these spines were green, and rose from greenish tubercles); all others from black ones. Length, 3.8 mm .

Third stage. If cad as before, except that on each vertex now appears a small, conical, black process. Shape of body as at previous stage; color black brown, the sides less dark than dorsum; the tubercles of the laterodorsal spines are pale buff on outer side, but black on dorsal side; the laterostigmatal spines have black tubercles, the infrastigmatal buff; the intermediate tubercles on anterior segments are yellow; the laterodorsal spines on the first thoracic segment are somewhat turned forward; but are no longer than others of same rows. Length, 5.6 mm .

Fourth stage. Head subcordate, much flattened frontally, and on the summit of each vertex is a small, sharp process as before; many small tuberenlations over the face, each of which sends ont a black hair; color of front head shining black, but the back is yellow. Color of body velvety black with a brown tint; spines much longer and heavier than before; the outer sille of tubercles of the laterodorsal rows is now dull yellow; the spines of laterostigmatal row have very little jellow at base, and those of infrastigmatal are yellow at base and a little way up. Length, 7.6 mm .

Fifth stage. Head as before, much flattcued; color black, orange at back. Color of body as at previous stage; spiues black, both the laterodorsal and laterostigmatal rery slightly colored, reddish yellow at base, scarcely visible except when viewed obliquely; the infrastigmatal and also the intermediate spines on anterior segments are all orauge at base, and abont half way up. In some examples the bases of lower spines and the back of the head were reddish yellow in the early part of this stage, but became orange later. Length, 12.7 mm .

Last stage. At first, the back of the head is a yellow orange. Color of body velvety black; the laterodorsal spines are drab at base, except those on the first two thoracic segments which are brownish yellow; all the spines of the other two rows are of same yellow as base, but the tubercles orange.

When full grown, the head is subcordate, deeply cleft, flattened in front, on each vertex a small, conical process; over the front many short, black hairs; color black, the back of head reddish yellow, sometimes dull yellow. Body cylindrical, of even thickness from the first to seventb abdominal segments, the segments rounded; color velvety black; spines long, slender, tapering, of about equal length; the long spines on first thoracic segment are directed forward, but are not longer than others; all the spines are beset with many short, black bristles; those of the laterodorsal rows are translucent brown at base, except on second and third thoracic segments where they are dull fellow; all of the others are dull yellow from base (including the tubercles) half way to top; tops of all spines and all the bristles black; legs and prolegs brown. Length, 35.6 mm . at rest; 45.7 mm . in motion; breadth at rest, 7.6 mm . ; length of laterodorsal spines in middle of body, 3.8 mm ; beight of supporting tubercle, 25 mm.

Chrysalis. Shape of S. diana, cylindrical, a little compressed laterally, the wing cases prominent and flaring at the base on ventral side; the whole surface finely corrugated; head case square, beveled at the sides, rounded transversely, the outline from top of mesonotum to extremity being arched; on either vertex a small, conical process; mesonotum carinated, followed by a deep, rounded excavation; on middle of either side of mesonotum a small, conical tubercle; on the abdomen two dorsal rows of similar tubercles and a row of small ones on each side; the color varies somewhat, some examples being red browu, irregularly mottled with black: on the wing cases red brown, and the black is limited mostly to the disks and nervores; others are drab and black, the wing cases fluely streaked with black, otherwise drab; on the abdomen
the front part of each segment is black, the rest drab, irregularly serrated at the junction. Length, 25.4 mm . ; breadth, 7.6 mm .

This butterfly oceurs in the upper Mississippi Valley from Michigan to Montana, and is said to have also been taken in Colorado. It does not appear to have been found north of our boundary, nor south of latitude $40^{\circ}$, and is fond of the open country.

Its seasons are similar to those of our eastern species of Argynnis, but in one season about ten per cent of the caterpillars hatched by Mr. Edwards from one batch of eggs, fed and passed one or two, and in one instance three moults, but all of these died before the middle of November. The eggs hatch in twenty-five to thirty days, and in one instance the caterpillars passed their first moult in the spring, four weeks after having been brought intö warmth, and their second in from fourteen to twenty-four days, while the precocious ones of the autumn spent only from five to seven days in their second stage. Mr. Edwards gives his experience as follows: "Nearly all the larvae became lethargie immediately after leaving the egg, having first devoured the egg-shells, but a few of a single brood in 1878, about ten per cent, fed and proceded to first and second moults. These gradually died off after first and second moults, but one lived several days after third, and died about 14th November. In the fall the first moult was reached at about eighteen days from the egg. The remaining larvae were kept in a cool room, and such as survived were placed in a greenhouse 14th Jan. on violet, and began to pass first moult 11th Feb., or after twenty-eight days." The chrysalis hangs for three weeks or more. The caterpillar feeds readily on violets.

## BRENTHIS HÜBNER.

## BRENTHIS FREIJA.

Papilio freija Thunb., Diss. ins. suec., ii :34, figs. 14, 14 (1791).<br>Brenth is freija Scudd., Proc. Bost, soc. nat. hist., xvii : 299-303 (1875).<br>Papilio freya Hübn., Eur. schmett., figs.

Imago. Body covered above with greenish brown hairs, toward the extremity fulrous; beneath ochraceous; palpi with mingled ochraceous and black bairs below, mingled fulvous and black above; stalk of antennae white below, black above, with white annulations; club of antennae black, bright fulvous at the tip.

Upper surface of wings rather deep fulrous, marked with black, with black nervures. Fore wings: a narrow, broken band extends transversely and very irregularly across the wing, commencing and terminating a little beyond the middle of the costal and inner border; its general direction is at flrst toward a point on the outer border, twothirds of the distance from the apex, next by a blind zigzag course toward the inner border at a point one-third of the distance from the base, and then straight toward the inuer border; it is made up first of a nearly straigbt band which reaches the upper median nervule, then by three short transverse dashes in the three succeeding inter-
spaces, the first midway between the termination of the band and the last divarication of the median nervure, the second below that divarication, and the thirdoutside of the second by its own widtlr; within the mesial band are three narrow transverse bands crossing the cell, the inuermost not reaching the median nervure; within these is a small lumule, opening outward; below the divarication of the median uervure is a short dash, suddenly bent inward, and then slightly upward; the extreme base of the wing is slightly dusky; at the outcr border is a broad band, regularly angulated on inner border, enclosing a scries of slender, transverse or linear, fulvous spots, seldom continuous, except at the apex, where they are larger; between this and the mesial band is a curved row of roundish spots, the lower one of which falls outside of the curve; at the apex this row merges into the outer band; between this band and the mesial there is on the costal border a dusky triangular spot, extending to the penultimate branch of the subcostal nervure. Hind wings: the mesial band extends, with a very irregularly zigzag course, from the middle of the costal border to a point between the subcostal and median nervures three-fifths of the distance from the base, and then, nearly at right angles, to the middle of the inner border; it is generally interrupted and then formed of five dashes: the first, in the costo-subcostal interspace, at a little less than one-half the distance from the base, is directed inward toward the inner border, about one-third the distance from the base; the second starting from outside the first crosses the subcostal nervule at right angles; the third at some distance outward crosses the subcosto-median and upper median interspaces, at right angles to the nervules; the fourth crosses the next interspace in the same gencral direction, but removed by its own width further toward the base; the fifth turned upward and starting just beyond the fourth, crosses the medio-submedian interspace; both the second and the third are occasionally bent; within this band, the subcostal nerrure is broadly bordercd with black scales from its divarication to its union with the median, and from the middle of the band so formed a band of equal width crosses the cell to the divarication of the median; in the middle of the cell is a rather large round spot, and in the costo-subcostal interspace is a black streak, parallel to the mesial band and midway between it and the base; the extreme base of the wing and the inner horder are slightly dusky; the outer black border of the wing is rather broad, and within it is a row of large triangular spots, separated from the border by a narrow fulvous stripe, sometimes broken into spots; nearly midway between the row of triangular spots and the mesial band, but approaching the former, is a curved row of rather large round spots in the subcostal and median interspaces. Fringe of outer border dark brown, interrupted with ochraceous.

Beneath: Fore coings pale fulvous, with the markings of the basal half and the row of round spots repeated conspicuously; apex pale cinnamon red, the tip and a streak on costal border midway between it and mesial band, ochraccous; the black border of the upper surface wanting and replaced by vers pale cinnamon red mingled with some ochraceous scales, the extremities of the nervules being ochraceous, tipped toward the round spots with large, triangular, scarcely sagittate, black spots. Hind voings: extreme base pale cinnamon red, with a white spot generally bordered with black between each of the principal nervures at their origin; at about two-fffths the distance from the base, a broad transverse band of pale cinnamon red crosses the wing, dusted profusely with ochraceous or white scales at its outer and inner limits, and especially where it crosses the spaces between the principal nervures; it is bordered within and withont with black; the inner black border starts from the costal nervure opposite its divaricatlon from the subcostal, crosses the interspace obliquely inward, takes a sweeping curve along the outer border of the cell back a little past the divarication of the median nervure, and crosses to the inner border by two crescents opening inward; the exterior border ls composed of three parts: the first starts from the middle of the costal border and crosses the costo-subcostal interspace in a straight line parallel to the inner border; the second starts from the subcostal nervure opposite the origin of the first, and crosses in a straight, sometimes broken, line the next two interspaces, nearly at right angles to the nervures; the third, starting from the lowest branch of the subcostal nervure, passes to the inner border by a series of crescents opening outward,
parallel in general direction to the inner border; the narrow outer border of the wing is pale cinnamon red, resting upon which is a row of transverse, ovoid, white spots surmounted by triangular, somewhat sagittate spots of (sometimes blackish) cimnamon red; between these and the broal band the space is pale cinnamon red with scattered ochraccous scales, which, on either side of the last median nervule, near its extremity, form a considerable ochraceous space, more or less mixed with reddish scales; but the space between the broad band and the outer"border is further occupied by a curving row of round, blackish spots, with intermingled reldish scales, bordered delicately with ochraceous; and also by a narrow, nearly straight band, slightly bent and less conspicuous in the middle, where it touches the outer border of the broad hand, and formed of pale rosaceous scales, whitish toward the extremities. Expanse of wiugs, 35.5 - 43.5 mm . Described from males only.

This species is very closely allied to B. montiuus, from which it difeers principally in the following particnlars; the color of the upper surface is not so deep; at the base and along the subcostal interspaces of the hind wings it is not so dusky; upon the lower surface the markings of the apex of the fore wings are much more conspicnous, as is also the broad mesial band of the hind wings, which here is of a rery ditferent tint from the base, while in B. montinus a difference is seldom, and then but slightly, discernible; the submarginal rows of sagittate spots and of round spots are also much more conspicnous, being frequently very nearly obliterated in B . montinus; the space between the arcuate row of round spots and the mesial band is much tinged in B. freija with rosaceous scales, giving it a peculiar appearance; these are present only in a slender band in B. montinns, and then are nearly obsolete; the darker parts of the outer border of the hind wings are darker than in B. montinus, being there somewhat pale cinnamon red, while here they are rather of cinnamon brown.

Freija is a circumpolar species in the strictest sense, being found on the northern shores of both worlds, and in each extending southward to the habitable zone. In the Old World its home stretches from Norway and Lapland to eastern Siberia, and in Russia it extends southward to the 60th degree of latitude. In the New World it occurs from Alaska to Labrador, where it is found upon both the eastern and the western coasts, and in the Rocky Mountain region extends as far south as Lake La Hache (Croteh), and Crow's Nest Pass, west of Ft. McLeod (Geddes). It is said by Edwards to occur in Colorado, but the speeimens obtained there by Mead (to which he probably refers) belong to the next species, while those from Port Arthur and Nepigon north of Lake Superior, referred by him to chariclea, belong here.

To judge from the eaptures north of Lake Superior it is a late species, flying late in August and early in September, or at the rery close of the season in that place. Eridently winter must be passed by the caterpillar just from the egg.

## BRENTHIS CHARICLEA.

Papilio chariclea Schneid., Nenest. mag. ent., v: 588 (1794).<br>Brenthis chariclea Scudd., Proc. Bost. soc. nat. hist., xvii: 297-299 (1875).<br>?Papilio tulliu O. Fabr., Fann. groenl., 192 (1780).<br>? Melitaea tarquinius Curt., Ross. voy., app.,

Argynnis boisduvalii Somm., Boisd. IconLép., i: 98, pl. 20, figs. 5-6 (1832).
Argynnis freya Edw., in his Catalognes. [Not. Pap. freija Thunb.]

Imago. Head and front of thorax covered with fulvous hairs; the upper surface of thorax and abdomen with brownish hairs, interspersed with fulvous upon the sides of the abdomen; below pale yellowish; palpi with pale hairs below, mingled fulvous and black upon the tip; stalk of antennae white below, black above, with fulvons annulations at the extremity of the joints; club of antennae black with narrow fulvous annulations.

Wings with the upper surface deep fulvons marked with black, with black nervures. Fore wings with a zigzag, wayy, occasionally broken band of moderate width, extending transversely across the wing, its inner edge starting at the middle of the costal border and terminating at the middle of the interual border; the general direction of the first third being outward, the second third nearly at right angles inward, the last third outward again nearly parallel to the first, but not turned so much outward; the band is formed, first, of a straight belt more or less irregular in outline, directed toward a point a little more than two-thirds the distance down the onter border, reaching the median nervure; second, either of two very deep lunules, the lower heaviest limh being parallel to the first band, or of two short, straight bands slightly connected above, having the same general direction, the lunules or bands occupying the next two interspaces; and third, of a broad shallow lunule or band occupying the next interspace and directed at right angles to the lower branch of the median nervure; the inner border behind the submedian nervure is $n p$ to this point dusky, as is the whole base of the wing nearly $n p$ to the divarication of the median nervure; within the mesial band there are three equidistant, transverse bands crossing the cell, and there is another short transverse blotch below the median nervure starting from between the two innermost of those above; the outer edge of the wing is more or less narrowly bordered with black, next to which is a row of triangular, slightly arrow-head shaped black spots, enclosing between it and the border a row of small, transverse, fulvous spats, which are nsually larger and sometimes continuous at the apex; midway between the band of triangular spots and the mesial band is a slightly curving row of rather large, sometimes squarish spots, the lower one of which falls a little outside the curve, and the upper ones merge at the tip into the band of triangular spots; midway between this row and the mesial band, there is on the costal border a triangular patch, extending, parallel to the mesial band, to the lower branch of the snbcostal nervure. Hind wings: the mesial band is directed first across the subcostal nervules at right angles to them, then sharply outward, reaching the upper branch of the median nervure at two-thirds the distance from the base, whence it turns toward the inner border with a sharply indented zigzag course, directed a little outward toward the anal angle; the whole base of the wing within this band is dusky, sometimes quite black, with the exception of from three to five irregnlarly shaped, variously sized, but generally small, fulvous spots upon the upper outer half; the markings non the apical half of the wing are almost exactly as on the fore wings, except that the cnrving row of round spots has a deeper curve, the spots are more universally ronnd, and increase in size toward the anal angle. The fringe of both wings is alternately light and dark brown.

Beneath: Fore wings pale fulvons, the markings of the basal half of the npper surface with the mesial band repeated, but with less distinctness, though there is no duskiness at the base, and the short streak below the median nervure just before its divarication meets a straight band coming at right angles from the junction of the
median and submedian nervures; the roundish spots in the curved row are smaller and more indistinct than above; covering that portion of the space between them and the mesial band, which is traversed by the subcostal nervures, is a triangular pale yellowish patch more distinct outwardly, with a transverse streak of pale cinnamou red aeross its middle; beyond the triangular pateh the wing is pale einnamen red, with a transverse streak of pale yellowish at the extreme apex; the sagittate spots are more delicate, and the nervules beyond them are distinctly yellowish or white. Basal half of the hind wings deep cinnamou red; there are three eharacteristic pearly white or silvery spots upon the basal half : the first is situated in the costo-subcostal interspace, its centre a little outside the divarication of the subcostal nervure; it is square or oblong, with the ends deeply excised and bordered with black, aud has the lower outer angle eut off by the upper subeostal nervule; the secoud is triangular, the sharpapex outward, and is situated between the approximating branches of the subcostal and median nervures, is traversed obliquely at one-third the distance from the base by the transverse nervule, and extends to the white band crossing the middle of the wing; its base is concave, deeply bordered with black, and extends at one side uarrowly along the lower edge of the subeostal nervure, reaching the first spot; the third, also triangular, oceupies the medio-submedian iuterspace; its base as far as the divarication of the median is thus united to the second spot, but is encroached upon from the inside by the cinnamon red of the base of the wing, which, crossing the median nervule, ocenpies about one-half of its area and forms in the outer portion a triangular spot bordered with blaek; there are two minute spots of white along the middle of the subcosto-median interspace, the outer with a blaek centre, and another at the base of the costo-subcostal interspace; the costal nervure also is edged above with white thronghout its extent; a narrow, zigzag black band extends across the middle of the wing, bordering the upper side of the second silvery spot on its course, itself generally very narrowly edged with white above; within this black band, next the inner border, the surface is frequently powdered with whitish or ochraceous scales; beyond the black band is another broader baud of white or silvery lunules whose general trend is nearly straight, but slightly curved; it rests against the onter angles of the black band along the inner half of its course, often indistinct near the middle, and broader and less defined upon the outer half; the spaces left between the black and silvery band at the outer half are ochraccous yellow between the subcostal nervules, and cinnamon red between the costal and subeostal nervures; the outer border of the wing is narrowly edged with black, and has silvery triangular or lozenge shaped spots situated between the nervules, tipped with sagittate black spots; the space between these and the silvery band is of a pale cinnamon red with seattered ochraceous seales. which indeed oceupy the greater portiou of the interspaces upon either side of the upper mediau nervule; the row of round black spots of the upper surface is repeated beneath, though often but indistinctly. Expanse of wings, $38.5-45 \mathrm{~mm}$.

This northern butterfly inhabits circumpolar lands on either side of the Atlantic, but extends much further sotithward on the western than on the eastern continent, being found on the latter only in Lapland, in the former not only in Greenland and Labrador, but in the west as far as Great Slave Lake, Crow's Nest Pass, west of Ft. McLeod (Geddes), and even Colorado (Mead), and in the east reaches the southern coast of Labrador, where it was taken by Couper at Natashquam. Edwards says it extends to the Pacific, but I have not scen it nor heard of any specific capture west of the Rocky Mountains.

Nothing is known of its seasons or history, except that it appears in Colorado early in the season, in May or early in June, according to Mr. Mead, so that winter can certainly not be passed as a caterpillar just from the egg. See also the notes on the preceding species.

# TRIbE MELITAEIDI. 

CHARIDRIAS SCUDDER.

## CHARIDRYAS ISMERIA.

> Melitaer ismeria Boisd.-LeC., Lép. Amér. sept., 168-169, pl. 46, figs. 1-4 (1833).

> Melitaea nycteis Edw., Proc. acad. nat. sc. Philad., 1861, 161 (1861).
> [Not Mel, nycteis Doubl.]

Imago. Head covered above with very pale brown and dusky hairs, behind the eyes heavily clothed below with white, above with mingled lighter and darker brown scales. Palpi silvery white on the basal half, passing beyond into brownish luteous, friuged below throughout, and abore on the apical half, with long black hairs, the apical joint with blackish recumbent scales. Antennae black brown, annulated heavily with white at the base of each joint, the white scales forming a continuous thread along the under outer line, and marking the entire under surface of the club, excepting the edges; otherwise the club is naked and luteous, but on its broadest part much iufuscated. Thorax covered above with mouse brown, clelicate hairs, with a tinge of olivaceous, beneath with sordid white hairs. Legs heavily clothed with white scales, becoming clay brown on the upper surface of the tibiae and tarsi and extremity of the femora; fore legs with long white hairs.

Upper surface of the wings black brown, heavily marked with pale fulvous. Fore wings with the cell mostly fulvous, but marked with black in ring-like markings enclosing a fulvous, at the base a fusiform, spot; crossing the middle of the cell a pair of complete attingent spots, the upper subcircular, the lower cordiform; outer limit of the cell marked with a black thread, beyond which is a slight fulvous bar; there is an extra-mesial, tolerably broad band of interrupted fulvous spots, composed of two portions, an upper which runs subparallel to the outer margin of the cell, from the costal margin to the median nervure, broadest in the middle and uarrowing at either extremity, but especially above; and of a lower portion of equal length, generally much broader in the middle than at the extremities, arcuate in form, its convexity inward; this is followed interiorly in the lowest median and medio-submedian interspaces by more or less fulvous, which sometimes includes the entire basal third of the medio-submedian interspace, but is then marked with a black longitudinal line returning upon itself; there is a sinuous series of subequal, round spots, white or fulvous in the upper half of the wing, fulvous in the lower, running subparallel to the outer margin, about midway between the extra-mesial band and the margin, but uearer if anything to the former; between this and the outer margin there is a greater or less number of interspacial spots, usually taking a more or less lunulate form, often obsolete, excepting that in the upper median iuterspace, which is almost always large, lunulate, sometimes with greatly elongated ends; these spots are of the same color as those preceding them in the same interspaces. Hind wings with irregular fulvous markings on the basal third of the wiug, not uniform in different individuals; a mesial, fusiform, moderately broad, fulvous band, cut by the fuscous nervules, and midway between it and the outer border a slightly orange fulvous band of more or less disconnected spots, when most widely separated circular, including, in the subcostal, sub-costo-median and median interspaces, a black, often faintly blue-pupiled, small, round spot; these are of fen followed externally by faint, powdery, whitish lunules, most
distinct ancl most extended in specimens showing the greater number of similar marginal markings on the fore wing, and especially in the female.

Beneath : fore wings pale fulvons, obscured with ashen and brownish fuscous in the apical half; the markings of the npper surface are vaguely repeated beneath, excepting at the outer margin; here they are somewhat different, cousisting of white or whitish sagittate spots in each of the interspaces; and, exceptiug in the upper median interspace, generally made up of a series of overlying sagittate spots, that is of arrow-heads containing more than one pair of barbs. Ifind wings gray brown, of a paler or deeper and warmer tint, often enlivened with variations in tone in different parts, hearily traversed with clull, silvery white markings, which are especially collected into a pair of transverse bands. besides the silyery white which margins the extreme base of the costal border and the inner border; the innermost of these crosses the middle of the cell and is narrow, and thinsts ont a tongue which runs to the extremity of the cell; the outer crosses the wing sliglitly beyond the midlle, marked near but not at its outer edge by an extremely irregular, zigzag thread of brown, which is more or less lunulate in form in each of the interspaces, but crosses both of the subcostal interspaces by a siugle augular marking, and the medio-submedian interspace with a single oblique line in continuation of the lower portion of the lnnule of the preceding interspace; at the outer border in each interspace is a silvery lunule, which is nearly transverse in all the interspaces excepting the upper median, where it is very large and high, and in all is followed ontwardly by a brown line, inwardly by a deep brown or blackish cloud, more or less extended; between these and the mesial silvery band a row of small, white-pupiled, black spots in most of the interspaces, in the medio-snbmedian interspace becoming a transverse, sigmoid bar. Expanse of wings $\delta, 37-40 \mathrm{~mm}$; 우, 44 mm .

Caterpillar. Last stage. Yellow, with blackish spines and three longitudinal blackish stripes. Head black, as well as the thoracic legs and the ventral surface; the other legs are yellow (Boisduval and LeConte).

Chrysalis. Ashen gray, with some paler light spots, and little dorsal tubercules nearly white (Boisdural and LeConte).

This butterfly is found over a wide cxtent of territory, being known south of Lat. $40^{\circ}$ from the Atlantic to the Rocky Mountains, and at the higher levels of the west, even into the heart of Colorado, and as far north as Montana and, according to Geddes, at Brandon, Manitoba.

Little is known of its history or how many broods there are, or how it passes the winter. It flies in June in Colorado, according to Reakirt, and the caterpillar, which is figured by Boisduval and LeConte, is said to feed on Helianthus trachelifolius. It awaite a biographer.

## SUBFAMILY HELICONINAE.

Heliconii pars Linn., Fabr., etc.; Héliconides pars Boisd.; Heliconidae Doubl.; Heli-
coninae Bates; Heliconina Herr.-Schaeff. Nereides Hübner.

Imago. Butterflies of medium or rather large size, with exceptionally elongated, slender bodies and elongated wings. Head large and broad.

Antennae inserted on the summit, not in a pit, exceptionally long and slender, straight, the joints so much elongated tbat there are rarely as many as forty joints in all, sparingly scaled, tbe club variable bnt rarely very broad, straight. Palpi rather slender, porrect.

Thorax rather slender; mesoscutellum angulate iu front, eutering the posterior face of the mesoscutum but little, never acutely ; posterior margiu paraboloid; metascuta and metascutellum as in Euploeinae.

Fore wings greatly elongated, rarely as little as twice as long as broad, the costal margin always pretty strongly arched. Costal nervure geuerally terminating near the middle of the outer half of the wing; generally one and only one of the four superior subcostal nervures emitted before the end of the cell; the latter is geuerally more than half as loug as the wing, completely closed, the lower closing rein sometimes weak.

Hind wings always rounded, usually laterally elougate but sometimes normal, always entire. Neuration very variable, the costal usually running free to the outer angle, sometimes conflueut with the subcostal for the greater part of its course, and running only half way to the angle; cell geuerally much elongated, generally closed; precostal recurver.

Legs very long and slender, the fore legs much atrophied, especially in the $\delta$, where the tarsus cousists of a siugle unarmed joint; in the female, though divided, it is unprovided with armature.

Abdomeu generally atteuuated, expanding apically in the male to give place to the large, papilioniform, tumid and rather simple clasps which are the most conspicuous feature of the appeudages.

Egg. Tall, nearly equal through the greatest part of its height, with gently couvex sides and subconoidal summit, with a moderate number of vertical ribs conuected by nearly as prominent, subcontinuous, cross lines, so as to form quadrangular cells not more than two or three times broader than high.

Caterpillar at birth. Head rounded and smooth with scattered long hairs. Body cylindrical with high and large papillae, bearing long and slender bristles, apically flaring, aud arranged on either side, at least those above the spiracles, in two priucipal rows in the middle of the segments, besides a row, between the others, of minute, bristle bearing papillae next the hinder edge of the segments.

Mature caterpillar. Head smooth, excepting for a single coroual spine on each hemisphere like those of the body. Body slender, cylindrical, somewhat moniliform, with several rows of excessively long, acnliform, and delicately and distantly spiuigerous spines near the middle of the segments, only the uppermost row contiuuing uniformly upon the thoracic segments.

Chrysalis. Of very bizarre appearance, with protnberant, apically very arcuate wiug-cases, more or less strongly produced and always appressed ocellar tubercles, a very deep and broad hollowing of the dorsum uext the base of the abdomen, with a corresponding elevation of the mesonotum and third abdomiual segment. Many tubercles, particularly upon the abdomen, may add much by their irregular develoment to the striking nature of the creature, which is still further increased by great variegation in the coloring.

This is one of the most interesting of all the subfamilies of butterflies, partly from its distribution, for though well cudowed with representatives it is confined to the New World, and mostly to the tropies, but also because its members are often the subject of mimiery by other butterflies. For without exception, I believe, every one of its members which has been tested in life has been found to be the possessor of odors so evil that they can be detected by the unskilled human nose, and since the butterflies are all of lively color, presenting exceptionally striking contrasts, it has been well argued that these are warning colors which signify their distasteful qualities ; or it may be that in view of their qualities, the possibilities of colorational design and magnificence have had fullest play. The most interesting paper upon this group is that by Pates on the spe-
cies of the Amazons, in which the theory of mimicry was first propounded (Trans. Linn. soc. Lond., xxiii). Regarding the position of this subfamily, some remarks will be found in the body of the present work on pp. 113-114.

## AGRAULIS BOISDUVAL AND LECONTE.

Agraulis Boiscl.-LeC., Lép. Amér. Sept., 142 (1833). Dione Auctorum (nec Hubn.).

Imago. Head moderately large, the face centrally tumid, rising beyond the level of the eyes, laterally with an oblique and sharp sulcus running to the onter base of the maxillae, and terminating above next the middle of the eye in a deep, abrupt, oval pit, directed toward the centre of the head; summit of head deeply and broadly sulcate mesially between the antennae, to a less degree transversely behind them; antennae rather longer than the abdomen, separated at hase by nearly twice the width of the second joint, composed of about thirty-eight joints, of which the third, fourth and fifth are of about equal breadth, the middle joints of the stalk lather more than three times as long as broad, the subreniform club composed of eleven joints, rapidly enlarging on the first four, then subequal and nearly four times as broad as long, broadly rounded at tip, only two or three joints entering into the diminution of size, the whole club about three times longer than broad and more arcuate within than without, strongly depressed. Palpi moderately long and slender, the apical joint minute, round, oval, not an eighth as long as the cylindrical, sinuous, middle joint. Eyes naked.

Fore wings elongate with arched costa, rounded apex, gently sinuate outer and hind margins; cell closed, about two-fifths the leugth of the wing. Subcostal nervure with four superior branches, the first arising a little beyond the tip of the cell, the others at equal distances from each other, the second nearer the third than the first, halfway between the tip of the cell and of the wing. Ifind wings rounded triangular, the costal and iuner margins of abont equal length, the outer margin moderately full, slightly crenulate. Cell open, the subcostal and median nervules somewhat approximate beyond it by the strong curvature of the upper branch of the latter, the subcostal forking at some distance before the median and very near the base.

Fore legs slender, the fore tibiae of the male scarcely half as long as the hind tibiae, the fore tarsus very slight, about three-fourths the length of the tibiae, composed of three joints of which the first is twice as long as the others together, the last lalf as stout and less than half as long as the middle joint, all unarmed and thinly clothed with hairs; hind tarsi a fifth longer than the tibiae, the first as long as the next three together, these decreasing regularly, the fifth as long as the second and a third longer than the fourth, all nearly naked and bristled above, armed beneath with four rows of fine and rather crowded, half recumbent spines, those of the outer rows growing larger from base to apex of each joint. Claws very long and slender, heeled at base, scarcely arcuate beyond, except for the downcurved point. Paronychia and pulvillus wanting.

Egg. Broad oval, slightly more than a fourth higher than broad, the sides pretty regnlarly convex, broadest scarcely below the middle, arching more rapidly near the summit; with about forteen straight, not greatly but equally elerated, vertical ribs, and crossed by considerably more than that number of straight, subcontinuous and very regular, slightly raised hands, as wide as the ribs, breaking the surface up into very regular quadrangular cells, half as broad again as high.

Caterpillar at birth. Head smooth and well rounded, with no protuberances, the npper half with scattered, forward projecting hairs, as long as the depth of the head. Body cylindrical, nearly equal, with series of exceptionally large, high, conical papillae, each bearing a long and slender, equal, apically expanding bristle, about as long as the diameter of the body, arranged in four rows on either side, viz. : a laterodorsal series centrally placed; a laterostigmatal centrally placed; an infrastigmatal postcentral series,
and a ventrostigmatal ante-central series. Besides these there is a miniature series of the same general nature, but so small as to be easily overlooked, which is supralateral, just in front of the incisures.

Mature caterpillar. Head small, smooth, subquadrate, the face strongly flattened, the front outer angle of each hemisphere prodneed, papilliform, bearing a very long and slender, feebly and delicately thorny spine, like those of the body. Body cylindrical, moniliform, nearly equal, but tapering in front so that the first thoracic segment is much smaller and not larger than the head, supporting three series of long and very slender, aculiform spines seated on low, smooth papillae which melt into their base, the spines distantly, briefly and very delicately spinulose; they are arranged as follows: a supralateral series, one to a segment on all the segments, that on the first thoracie segment reduced to a mere conical papilla and bristle; a suprastigmatal series and an infrastigmatal on all the abdominal segments, all a little in advance of the middle, besides on the hind thoracic segment a single stigmatal spine at the anterior edge.

Chrysalis. Of an odd shape, as if formed of two very different subequal masses, one formed of the straight, tolerably regular, conical ablomen; the other of the straight, but very irregular remainder of the body, obliquely attached to the base of the abdomen; the ocellar prominences are rounded, obliquely compressed lobes, with denticulate margin and of no very great size ; the basal wing tubercles form an anterior, conical, papilliform prominence, and a rounded and pinched lateral ridge; the mesonotum high, regularly and considerably arched, the metanotum and base of abdomen as considerably hollowed; the extremity of the wings protuberant, strongly rounded. There is on the abdomen a supralateral series of conical tubercles, particularly on the third segment, where they are largest and double, and on the fifth, sixth and seventh segments, where they decrease regularly in size; there are smaller, blunter, supralateral tubereles on the third and fourth segments, and on the front edge of the fiftl to seventh segments a similar small one. Cremaster stont, the apical field of hooklets large and quadrate.

This is a tropical American group with very few species, one of which is common enough in our southern states. The external resemblance of the butterfly to the Argynnidi has led to its being long regarded as belonging with that group, which a study of the early stages was the first to show to be erroneous. The transformations of our species were figured long ago by Abbot, and have within a few years been minutely described by Edwards, but the earliest stages not quite accurately. The caterpillars are remarkably rapid in growth, and in Mr. Edwards's opinion there must be a large number of generations annually.

## AGRAULIS VANILLAE.

Papilio vanillae Linu., Syst. nat., ed, x: 482 (1758) ;-Stoll', Suppl. Cram, pap. exot., 7 8, pl. 1, figs. Ta, b (1791);-Sepp, Pap. Sur., $1 \mathrm{i}: 17-18, \mathrm{pl}$. $\overline{\text { 万ै ( }}$ ( 848 ).
Dryas phalerata vanillae Hübn., Samml. exot. sehmett., i (1806-1816).
Dione vanillae Hübu., Verz. bek. schmett., 31 (1816).

Agraulis vanillae Boisd.-LeC., Lép. Amér. sept., 143-145, pl, 42, igss. 1-4 (1833);-Edw , Can. ent., xii :122-126 (1880);-Freneh, Butt. east. U. S., 148-150 (18S6).
Papilio passiftorae Fabr., Ent. syst., iii: 60 (1793) ;-Smith-Abb.. Lep. ins. Geo., i: 23-2t, pl. 12 (1797).

Imago. Head covered above with bright orange red hairs, eulivened by a few white ones, especially in a spot at the outer base of the antennae, and by a pair on either side behind the upper margin of the eyc, and by a collar of white around the lower half of the eye. Palpi pure white without, orange red within; the onter half
of the middle joint and the whole of the apical joint black above; over the whole a few scattered black bristles. Antenuae dead black with a few inconspicuous white scales at the base of each joint above, a little more conspicuous on the club; the club on its inner naked surface castaneous. Thoras covered above with orange red hairs, beneath with pure white bairs, excepting in two longitudinal, small, oblique streaks apparently covered by the middle and hind femora when these are closely packed beside the body; all the legs cinnamoneous ahove, the femora white beneath; most of the spines blackish.

Wings orange tawny, brighter and deeper in the male than in the female; all the veins of the fore wing marked in black, becoming rather fuscous in the basal fourth of the wing; two round, white pupiled, black spots in the cell, one in the middle of the upper half, the other just outside of it against its lower edge; outer margin of the cell marked by a pair of similar spots, usually confluent, and so forming a black bar depending from the subcostal nervure, broad above and tapering below, with a line of white scales in the centre of the part corresponding to the upper spot; a row of three oblique, roundish oval spots, the middle one a little outside the line, in the middle of the median and medio-submedian interspaces in the outer fourth of the wing; veins, especially those below the superior subcostal nervules, heavily bordered with blackish brown, in the median and submedian nervules expanding into a round apical spot, giving the nervules the appearance of large-headed pins. Hind wings with a broad black border, more distinct in the upper than in the lower half of the wing, enclosing in each of the interspaces a large, round or roundish, tawny spot, so large as often nearly to interrupt the band; just beyond the middle of the wing in the upper subcostal and upper median interspaces, and especially in the former, is a large black spot of irregular form and a small triangular spot at the extreme base of the subcostal interspace.

Beueath: fore wings of the same color as above but the whole apex of the wing changing to a dark olivaceous brown; the black spots of the upper surface not marginal are repeated beneath more or less distinctly, and are always accompanied by a large silvery pupil, excepting the spot in the medio-submedian interspace and ofteu excepting also that in the lower median interspace; the dark olivaceons apex is marked near its interior border and next the upper margin with long streaks of pale straw yellow which often run in fine lines down the interspaces, but it is more conspicuously marked with a number of brilliant silvery spots often finely black-edged, of which the most important are three, two in the next to the lowest subcostal interspace aud one in the subcosto-median interspace; a small spot in the last superior subcostal interspace is circular, all the others are more or less elongated; the cloudy black markings which repeat vagnely those of the upper surface at the extremity of the lower median nervules are often enlivened also by silvery spots. Hind wings dark brownish olivaceous, very brilliantly variegated by large and conspicuous glistening silvery spots; there is one near the base of the margino-costal, costo-subcostal, subcosto-median, mediosubmedian, and internal interspaces, in all cases but the costo-subcostal interspace as near the base as possible and with that same exception all very much elongated and all black-edged; in the middle of the upper subcostal interspace is a very large, long oral spot cut above in the middle by a broad and deep incisure, sometimes entirely, always nearly, severing the spot; in the medio-submedian and submedio-internal interspaces are a pair of long oval spots, broadest nest the base, the tip of the outer one nearly or quite reaching the margin of the wing; in the median interspaces is a pair side by side, that in the lower median interspace in the middle of the interspace, that in the upper nearer the base, also elongated, but that in the lower median interspace to a greater extent; all these spots are black-edged; they are followed by a marginal series of silvery lunules of considerable inequality in size, that in the interspace beyond the cell being particularly large, ruming half way toward the extremity of the cell and more or less club-shaped. Abdomen above of the color of the upper surface of the wing; beneatli and at the sides white with a lateral orange line. Expanse of wings. $70-78 \mathrm{~mm}$.

The following descriptions of the early stages are those of W. H. Edwards, altered only to conform to the present work:-

Egg. Conoidal, truncated, the top a little arched; the sides more or less convex, varying; the height to the brealth as nine to seven; marked by fonrteen straight ribs, which are compressed and elevated, and run from base to top; crossed by abont eleven striae.* horizontal, rather prominent; the spaces between the ribs and striae are quadrangular, the shortest side being with the long axis of the egg; these spaces are depressed and are either flat or slightly conver; the summit is covered with rows of cells, concentric, those of the onter two rows large, hexagonal and irregnlar, of the third row small, hexagonal; within these are cight small cells, not depressed, irregnlarly rhomboidal and forming an eight-rayed star; in the centre a minute star of six rays. Duration of this stage four to tive days.

Caterpillar. First stage. Nead nearly globular, flattened on lower front face; color brown; slightly pilose. Body cylindrical, thickest at first abdominal segment, tapering slightly to tail, the segments well rounded; color brownish orange, glossy; on either side the dorsal line on each segment after the middle thoracic segment is a laterodorsal row of short, conical, pale black tubercles, and two similar rows on either side, forming transverse rows of six tubercles, from the top of each of which springs a short, black hair; on first thoracic segment is a black, dorsal collar, with fine tubercles; legs brown. Length, 3.6 mm .

Secondstage. Head obovoid, the sides quite convex, the face flattened, the top depressed, and on each conical vertes a simple, black process very similar to the body spines, but less tapering and much shorter, pointed at top and ending with a short, fine bristle; others disposed abont it just as with the spines; a few hairs, long and short, on front face; color chocolate brown. Jody same shape; nearly same color, less brown, more orange; armed with six longitudinal rows of long, tapering, black spines, at top subconic, each ending in a fine, short, black bristle; a few similar bristles abont the spine from base up; on first thoracic segment a clark chitinous collar, broken at the dorsal line, and bearing minute, hairy tubercles; legs black. Length, 6 mm .

Third stagle. Head as at second stage, glossy black; the vertices rather high, couical; the processes two-thirds as long as the dorsal spines on middle thoracic segment, irregnlarly tapering, slightly bent back, conical at top. Color of body dark (or red brown) orange, glossy; between supralateral and suprastigmatal spines a greenish brown band, not well defined, rather a discoloration, and about the seventh abdominal segment fading away; the spines long, all black and shining, from black tubercles; those of supralateral rows on last two thoracic segments longest, those of stigmatal rows on the first two thoracie segments nearly as long; collar on first thoracic segment black. Length, 7.6 mm .

Fourth stage. Head as before, but the rertices higher, and the processes longer and much recurved, resembling horns; face black on front, behind the lyead orauge, but from base of each horn a black stripe passes down the back of the head; on the front are fire minnte orange spots, one at base of each horn, and three in a cross row below. Color of body now dark orange, glossy; a mediodorsal stripe of olive brown ; a broad band of same hoe flls the space between the supraiateral and suprastigmatal spines from the first thoracic to the ninth abdominal segments, the lower part of body also olive brown, so that the orange is restricted to the dorsal area and lower part of sides; in some examples the band is macular, orange showing in it. Length, 20 mm .

Last stage. [Soon after change.] Color of body red orange, the mediodorsal stripe greenish, the lateral band pale black, and broadened, so as to come to the outer sides of the tubercles of the two rows; the base same color as the band; the orange restricted to a narrow band rouning with the spiracles. Length, 24 mm . Twentyfour lours after this monlt the length was 30 mm ., and one day after this was 38 mm .
[Wheu full grown.] Head obovoid, deeply cleft, with high conical vertices, on each of whicb stands a stont, spinons, reeurved process, 38 mm . long, black, in all respects formed like the body spines, except that it is less tapering, the upper two-thirds being of abont uniform size; the tip conical and giving out a short, fine bristle; a few other

[^4]like bristles about the sides; sides and back of head rounded. but the front much flattened; sparsely pilose; color of front black, with two vertical orange stripes, one on either side of and very near the sutme; color of hind head, between the horns and down the sides greenish yellow, the lower part of the side black; also a black stripe runs back from base of the horn. Body cylindrical, thickest from middle thoracic to first abdominal segments, tapering to the uinth abdominal segment very gradually; furnished with six rows of long, tapering black spines, bluntly conical at top, from which springs a short and fine black bristle; a few similar bristles irregnlarly placed abont each spine from base to top; . . over the legs on each side of the thoracic segments is a black tubercle with hairs ; the spines of supralateral rows on the anterior segwents are longest, measuring 4 mm . ; the snprastigmatal spines are quite uniformly 2.8 mm , and the infrastigmata! 2.3 mm ; color red-orange, with a broad mediodorsal band of greenish black and a broad, slate black band which occupies the space between the supralateral and suprastigmatal spines, and reaches to the farther sides of and embraces the tubercles of these rows; the base of body slate black, so that the orange is restricteclabore to two narrow stripes lying between the dorsal and the lateral black bands, and to another stripe ruming with the spiracles (these bands widened much after the monlt and as this stage proceeded), the thole upper surface highty glazed; all the legs black. Length, 38 mm . g greatest breadth, 6 mm . There was some variation of color at maturity; some larrae had a gray line or stripe below spiracles; on one this line was white and extended the whole length, in another it disappeared at the first abdominal segment; the color of the dark band on upper part of side was greenish black, or slate black, varying with the point of view. From fonrth moult to suspension fiftynine to seventy-two bours; from suspension to chrysalis thirteen to fifteen hours.

Chrysalis. Long, slender, the thorax much compressel laterally, and the wing cases very prominent, forming a narrow carinated hunch, which rounds abruptly on posterior end; bead case high, cylindrical, compressed transversely, the top sloping on the ventral side at about $45^{\circ}$; on each rertex a short ( 1.3 mm . long), ear-like process, excavated on the dorsal side, and creuated at the top; between these the top of head is twice incurred; at the base of head case, on dorsal side, a depression; the mesonotum large, prominent, compressed, carinated, followed posteriorly by a deep and broad depression; wing cases smooth, a little flaring at base, depressed in middle; abdomen slender and tapering; a row of minute, mediodorsal tubercles, and on either side of these a row of large, rounded ones, those of the anterior segments largest of all, and compressed laterally; colors very variable, some examples are buff with greenish markings, or on the abdomen greenish brown; the head and wing cases buff, the former with a slight red tint; on the depression at base of head case is a patcb of clear pale pink on either side the dorsal Jine, and betreen, as also at the outer edges of these patches is a little black; top of head case pink and black, the processes dark brown at top and on dorsal side; mesonotum buff, mottled green, as is the dorsal side of abdomen; wing cases buff, with a greenish patcb on middle and a stripe running with one of the interspaces of the wing next margin; on side of abdomen a reddish buff stripe, and below this a broad, greenish brown band; on ventral side a clear pink patch from end of wings down. Some were rery black, the wing cases and anterior parts mottled in light and dark black; some had the wing cases, mesonotnm and head case pink tinted, mottled all over with greenish.black; the ventral edges of wing cases clear, pink buff; in all examples the two pink spots at base of head case and the stripe on abdomen appear, and in all there is a black, angular inscription like figure 3 or like $V$, on the rentral side of the wing case, about one-third the distance from base to end. Length, 26.7 mm . ; depth, 8.6 mm . ; breadth at base of wings, 6.6 mm ; at abdomen, 5 mm .

This butterfly, common euough in our southern states, has an immense distribution, being found southward upon continent and island as far as Argentine Republic, though Bartlett-Calvert does not include it in his list
of Chilian butterflies. In the United States it extends from Atlantic to Pacific, but not often north of $35^{\circ} \mathrm{N}$. Latitude, though it occurs sparingly and occasionally as far as Pennsylvania and New Jersey on the Atlantic const. Edwards says that on only two occasions have single specimens been taken in West Virginia.

There are many broods of this brilliant butterfly in the course of the year. As early as the end of March, Riley found eggs and caterpillars of all stages in sonthern California, so that it would probably be impossible to determine how many broods occurred in the year, for the caterpillars mature with great rapidity, the later stages being exceptionally brief, so that the whole round from egg to imago was accomplished in twenty-three days in one instance related by Mr. Edwards, and in another in twenty-one days. Dr. Wittfeld also writes me of butterflies appearing July 26, from eggs laid the first of the month. How the winter is passed is nowhere stated.

Dr. Wittfeld writes that the eggs are deposited chiefly on the tips of the leaves of the food plant, from one to six or eight being laid on one leaf; even if the leaf tips are already full of the eggs of its ally, A postraphia charithonia, say from five to eighteen of them, Agraulis will lay hers close beside them; "in fact Agranlis is very injudicious and will deposit her eggs on dry grass, forty feet away from the food plant." Riley once saw the female laying eggs, which she did, when undisturbed, at the rate of seven eggs a minute; the eggs hatch in four or five days.

The caterpillars are very hardy and easy to raise, Dr. Wittfeld tells me ; they feed on Passiflora incarnata in the United States, and other species of Passiflora further sonth, and when full grown will often travel great distances to suspend, and then do so on dry sticks, fence rails, etc., fully exposed to view. The chrysalis state lasts in several recorded instances as follows: in West Virginia, July 5-12 (Edwards) ; in Georgia, July 9-17 (Abbot) ; in Florida, July 18-26 (Wittfeld) ; in Surinam, May 28-June 1 (Stoll'), six to eight days (Sepp), so that it may hang from four to eight days.

Dr. Wittfeld says he has seen from six to sixteen butterflies roost with closed wings on one bunch of grass.

According to Sepp the caterpillars and chrysalids of the two sexes may be distinguished by their color, but probably he judged from insufficient material, there being considerable individual variation. Dr. Riley observed that the full grown caterpillar he found in California "differed very much in colorational aspect from those which I an familiar with in the east. Instead of being uniformly vinous brown, it was of a beautiful leaden, or pale indigo-blue, with distinct, lateral, white stripes, and the black head was also marked with white; whereas in my eastern specimens the head is uniformly black."

This caterpillar is attacked in Missouri, according to Riley, by Chalcis flavipes ( $88: 14,15$ ) and Pteromalus puparum $(89: 1,2)$, and Judge Thomas has also raised the former from it in Georgia.

## LYCAENIDAE.

# SUBFAMILY LYCAENINAE. <br> TRIBE THECLIDI. 

## CALLICISTA GROTE.

| Callicista Grote, Bull. Buff. soc. nat. $s c_{o}$, iil: | Tmolus pars Butler. |
| :--- | :--- |
| 107 (1876). | Thecla pars Auctorum. |

Imago. Front of head seen from the face of the same width as one of the eyes. Eyes moderately full, sparsely, briefly and uniformly pilose. Antennae very delicate, balf as long again as the abdomen, separated at base by three-fourths the width of the front of the head, composed of about thirty joiuts of which eleven or twelve form the long ovate compressed club, which is three and a half times as long as broad, broadest beyond the middle, increases very regularly in size on the basal half, hut terminates more abruptly in a slightly produced, rounded, naked tip, into which four joints enter; the broadest joints are about five times as broad as long, and about five times as broad as the stalk where the longest joints are about five times as long as broad. Palpi if appressed to the head would just fail of reaching the base of the antennae, slender, the apical of about the same length as the midllle joint and rery slender.

Outer margin of fore wings sinuate, the neuration not affected in the male by the presence of the discal spot, being the same in both sexes. Cell half as long as the wing, truncate at tip and scarcely narrower thav in the middle, the lower half closed by a feeble vein, the origin of the subcostal and median nervures much as in the female of Mitura. Hind wings with well rounded outer border, the lower median nervule produced to a thread-like tail, the outer two-fifths of the inner margin roundly and angularly excised. First median fork nearer the base of the wing than the subcostal fork.

Fore tibiae three-fourths the length of the hind tibiae, of the same length as the fore tarsi; the latter, in the male, bearing at the tip only a pair of downturned, scarcely arcuate spines, barely larger than the other spines. Hind tibiae and tarsi of equal length, the latter, excepting the apical joint, armed beneath with crowded, slender spines, excepting on the basal half of the basal joint very long, much longer than the width of the tarsi. Claws minute, bent with a rounded curve in the middle, finely pointed; paronychia broad at base and rounded with an inferior, upcurved, delicate, equal, compressed fiuger, half as long as the claws.

This genus is confined, so far as I know, to only a single species, whose range is given below ; it is by no means impossible, however, that Central American forms, which I have not been able to examine, are to be referred here. Nothing is known of the earlier stages.

## CALLICISTA COLUMELLA.

Hesperia columella Fabr., ent., syst., iii: 282 (1593).<br>C'allicista columella Sculd., Bull. Bulf. soc. uat. sc., iii :107 (1876).<br>Thecla columella French, Butt. cast. U.S., 271-272 (1886).<br>Tmolus eurytulus Hübn., Samml. exot. schmett., ii (1822-26).<br>Thecla eurytulus Gorm.-Salv., Biol. centr.

Imago. Head with the front pure white, tufted above with black, white and orange scales, the orange in a transverse line behind the antennae. Palpi white, the apical joint brown above. Antennae black brown, annulated at the base of the joints with white, excepting on the clnb; the three or four apical joints of the club orange.

Above: fore wings uniform dark brown, the outer margin with a black thread; fringe blnish white; the males with a quadrate black brown spot of special scales at the extremity of the cell, a little longer than broad, as loug as the width of the cell; extremity of the cell marked in the female by a faint black bar. Hind wings of the same color as the fore wings but much suffused with blue, by scattered blne scales along the lower half, especially in the female; lower half of the wing with a pre-marginal series of round, blackish brown or brown, circular spots, that in the lower median interspace the largest and darkest; margin edged finely with black; fringe as above; the tail black, white-tipped.

Beneath, soft uniform slate brown; fore wings with a post-mesial bent series of slender white lnnules edged to nearly the same depth externally with black brown; a marginal series of circular, pale brown spots, each surrounded by a faint, pallid annulus and followed interiorly by a series of pale brown lunules and these in the upper half of the wing by yellow sagittae; edge and fringe as above. Hind wings with a very irregular, interrupted, sinuons, mesial series of black spots encircled with white exteriorly and edged interiorly with orange; near the base of the cell and of the costosubcostal interspace, largest in the latter, a round, black spot enlivened with orange scales and anuulated with white; all of these markings are minute; the outer border is marked in a manner similar to that of the fore wing, excepting that there is a large, conspicnous, black spot in the lower median interspace, occupying the entire width of the interspace, followed interiorly by an orange lnnule, and a similar shade of orange sometimes follows the smaller white-capped spot in the upper median interspace, and a streak of orange follows in the same relation over the interspaces below. Expanse of wings, $26-29 \mathrm{~mm}$.

This pretty butterfly belongs to the southernmost parts of the United States where it is found from Florida, including the Keys, and Georgia to Texas. It is also found beyond our territory in the Antilles and Mexico and even to Guiana, the Amazons and eastern Brazil. But that its northern extension may be greater than known is indicated by its eapture near Buffalo, N. Y. by Reinceke.

The Buffalo specimen was taken July 13 and Maynard took it in southern Florida, December 25 ; beyond this we have no knowledge of the history of the species. Mr. Maynard says it is of retiring habits, frequenting the edge of shrubbery and keeping generally in its shade.

## CALYCOPIS SCUDDER.

Calycopis Sculd., Bull. Buff. soc, nat, se., iii: 105 (1s76). Thecla pars Auctormm,

Imago. Front of head narrower than the face view of the eyes. Eyes moderately full, sparsely and briefly pilose, the pilosity briefer below than above, but otherwise uniform. Antemae delicate, half as long again as the abdomen, separated at hase by almost or quite the width of the front, composed of thirty joints of which trelve form the long fusiform club; this is largest in the middle, tapers about equally toward either extremity, the tip rather blnntly pointed, about fire or six times as long as broad, the middle joints about three times as broad as long, four times as broad as the stalk where the longest joints are about five or six times as long as broad. Palpi short; if appressed to the front they would fall far short of the base of the antennae, the last joint only moderately slender, apparently about three-fourths the length of the middle joint.

Outer margin of fore wing gently arcuate. Cell reaching the middle of the wing, the limiting external reins exceedingly and equally slight, transverse, the origin of the nervures much as in the female of Mitura, but the first branch of the median arising nearer the base than that of the subcostal nervure. Hind wings with the curve of the outer border not quite regular, being nearly straight in the middle, the middle and lowest median nervules developing a filiform tail of unequal length, the anal angle scarcely lobed and preceded on the inner margin by a slight oblique excision which is scarcely concare. First divarication of the median nervure considerably nearer the base than that of the subcostal.

All the legs very short, the fore tibiae and fore tarsi of equal length in the male, and about two-thinds as long as the hind tibiae or hind tarsi; the fore tibiae of male broken into the ordinary joints, armed apically only with a pair of downturned spines, differing in no respect from the other tarsal spines. First hind tarsal joint as long as the rest together, the under surface of the whole tarsus armed with delicate spines, infrequent on the basal, frequent on the apical half of the tarsus. Claws very small and delicate; paronychia slender, filiform, as long as the claw but nearly straight; pulvillus bullate.

This genus comprises at least half a dozen Central American forms and perhaps some additional South American, ranging at any rate from the middle of the United States to northern Sonth America, as far as eastern Brazil. Their transformations are unknown, though it is apparent that Abbot reared the single species which occurs in the United States.

## CALYCOPIS CECROPS.

```
    Hesperice cecrojs Fabr., ent. syst., iii: 2%0
(1793).
    Calyconis cecrops Scudrl., Bull. Buft. -oc.
nat. sc., iii: 10S (18%6).
Fiusticus armatus poeas Hibbn, Samml. exot. schmett., i (1806-16).
```

Thecle pneas Boist.-LeC.. Lép. Amér. sept., 111-112, p\}. 35, figr. 1-4 (1833) ;-French, Butt. east. U. S., $270-271$ ( 1 ss 6 ).

Strymon bean 1Iübnı, Verz. bek, sehmett., io (1816).

Innago. Head with the face brown, edged laterally with brilliant white, tufted above witl black scales; the eye encircled with white. Palpi black brown, anmmated with silvery white. Antennae biack brown, distinctly and rather broadly aunulate with white at the base of each joint and over the whole of the base of the chub, which otherwise is velrety black with an orange tip. Thoras corered above with dark brown hairs, many of them with a bluish tinge, beneath clay brown. Legs black, conspicuously annulated with white.

Above: fore wings uniform rich blackish brown, with a faint bluish reflection, in the female with a more distinct pale glaucus blue reflection from the inner two-thirds of the lower half. Hind wings the same, the lower half of the wing below the upper limit of the median nervure overlaid with dark blue, with the exception of the marginal markings becoming less distinct and paler in certain reflections, in the female always with more or less of a glaucous tint; the outer margin has a distinct black thread, preceded in many eases by a similar white thread, and this in the median and medio-submedian interspaces by a large roundish brown spot, free of blue scales; and finally, at the extreme anal angle, a minute orange spot or streak, surrounded by black and preceded by white; tails black, largely white-tipped.

Bencath, rather uniform pale slate brown, with a slight tint of buff. Fore wings with a straight orange line parallel to the outer margin running from the costal border to the lowest median nervule, striking the latter exactly in the middle; this line is finely edged externally by black and then by white; midway between this transverse line and the outer margin is a faint, sometimes obsolete, fuscous line in the subcostomedian and median interspaces; outer limit of the cell faintly marked by dusky scales. Hind voings with the outer limit of the cell marked as in the fore wings, but more distinctly and sometimes enlivened with orange; the straight orange line of the fore wings here becomes broader and generally darker and exceedingly irregular ; as before, it is edged exteriorly with black and then with white, and on the lower half of the wing the white edging is again edged with black; its course may be described by following the direction of the white line; this crosses the upper interspaces as far as the upper median nervule exactly at its middle, as before in a very nearly straight line, occasionally shifted slightly in position at the nervules; it crosses the upper median interspaces in a straight, oblique course, as if its upper portion had been thrust inward nearly half way to tbe base of the interspace; it crosses each of the next two interspaces in a curved line bent toward the base at somewhat less than a right angle, and the lowest interspace in an oblique line directed inward; in the interspaces where the line is bent it encloses externally in the bent portion as much orange as lies internally; there is a marginal series of more or less ocellated spots, often obsolete in the upper half of the wing, but when present consisting of cloudy markings, of which the most distinct is a brownish anmulus; but in the lower half of the wing, where the orange stripe is most variegated, these spots become large and conspicuous and ordinarily bright colored; they vary greatly, but are usually much variegated with orange, though sometimes not a trace of this exists; the spot in the lower median interspace is the most conspicuous and largest, and is either a blackish brown lunule in a pale brown setting, followed above by an arcuate black brown streak, or the black may be reduced and intensified and broadly surrounded by briglt orange in the place of the pale brown, followed as hefore by a black arcuation; in the medio-submedian interspace the black is intensified and powdered with blue scales, and orange is rarely found excepting in continuation of an oblique streak which crosses the interspace next the inner margin, followed above by a sleuder thread of black, and this by white, and below at the anal angle by a small, round black spot, edged without and within with white. Expanse of wings, $21-28 \mathrm{~mm}$.

This exquisite little butterfly is one of the many delights of the south. It is found from West Virginia and Kentucky southward, occasionally a little further north, and extends westward to the Great Plains. It reaches also beyond our borders, being found in the West Indies, Mexico, Guatemala and even Panama.

Nothing whatever is certainly known of its history or carly stages, but in Florida it flies early in February. Abbot distinguished in his notes between three kinds of "purple hair-streak" butterflies: a
"great," a "small" and a "lcast," which in all probability refer respec tively to halesus, m-album and cecrops. If, then, his "least" be cecrops, as is certainly highly probable, then he bred the butterfly in Georgia May 20, after twenty days in chrysalis, from a caterpillar feeding "on the large blue huckleberry," doubtless some species of Vaccinium.

## THECLA FABRICIUS.

## THECLA LORATA.

Thecla lorata Grote-Rob., Trans. Amer. ent. soc., i: 171-173 (1s6\%).
Imago. "Male.-Allied to Thecla falacer, Bdv. and LeC. Head black; eyes circled narrowly with white; antennae black, annulate with white, the 'club' eutirely black. Body above, black, the longer scales on thorax and abdomen with a paler somewhat brassy tinge. Beneath the abdomen is whitish, the under thoracic squamation is blackish gray; legs mostly whitish, blackisl outwardly, subannulate, the tarsi touched with fuscous inwardly.
"Upper surface of wings of a uniform black or blackish, with a subdued brassy-brown reflection which becomes prominent in certain lights. An ovate sexual spot on the disc of primaries. Secondaries with two very unequal tails as in T. falacer, the lower the longer, fringed with white. Base of the fringes, from anal angle to the lower 'tall,' White, and at this place is a narrow, white, interual line in one specimen. Between the 'tails,' the fringes, which elsewhere are dark, are tipped with white.
"Under surface somewhat paler than upper, brownish black. An extra-basal common streak, composed of powdery dark blue scales, runs across both wings; this is slightly irregular, and is lost inferiorly among the longer scales which clothe the internal margin of the secondaries. Two short white lines on the disc of primaries enclosing an incomplete darker shaded spot or space as in allied species. Beyond, an interrupted, extra-discal, semilunated, white line, narrowly edged within by blackish scales and preceded by dark interspaceal shadings. An incomplete, bluish-white, subparallel, subterminal line, edged outwardly by blackish seales. Secondaries with two short, parallel, white lines on the disc, enclosing an analogous space to that on disc of primaries. An extra-discal semilunated and interrupted white line as on primaries, preceded by dark interspaceal shades; these are faintly edged within in one specimen by white scales, so that here the white line may be said to be geminate, enclosing a dark shade; on the subcostal interspace the series is interrupted, the lines being severed and brought nearer to the base of the wing, a detached spot is thus formed as is usual. A subterminal bluish white line, forming prominent lunules on the interspaces inferiorly, edges outwardly with black; along anal angle the black scales are followed by a fulvous streak, this by first white then black scales. Outside of the black scales edging the suhterminal line on the next interspace above, is a patch of powdery blue scattered scales extending to the external margin; on the interspace above is a distinct, fulvons crescent, succeeded by black scales on the margin; the fulvous scales are faintly continued on the nest succeeding iuterspace, which also shows a ferw scattered bluish-white scales. A narrow white line lies directly on the margin. Expanse, 1.2 inch. Length of body, . 6 inch."

No one seems to have found additional specimens of this species, described from two males from Virginia, and accordingly $I$ reproduce the original description. Possibly the species is not distinct from $T$. calanns, but I have never noticed in the latter the delicate line of blue scalcs near the base of the wings beneath, which appears to be a characteristic mark of the present form.

## EUPSYCHE SCUDDER.

Eupsyche Scudd., Bull. Buff. soe. nat. se., iii: 112 (1876). Thecla pars Anetorum.
Imago. Head moderately large, compactly sessile. Front as broad as the face view of the eyes. Eyes rather fuller than usual, with a very sparse pilosity, so brief as to be scarcely perceptible. Antennae unusually short, being less than half the length of the fore wings and not very much longer than the abdomen, separated at base by hardly more than half the front, composed of not far from forty joints; the club very long and slender, and arising very gradually, so as to be difficult to delimit, but it is composed of not far from eighteen joints and is scarcely more than twice as stont as the stalk, bluntly rounded at the tip, which does not otherwise taper, and occupies nearly a third of the whole antenna; in the middle of the club the joints are less than twice as broad as long, and in the stalk the longest are not more than four times as long as broad. Palpi slender and rather long, the last joint very slender and elongated, as long as the middle joint, and if appressed to the head would surpass the base of the antemnae.

Thorax unusually plump, the fore wings shaped much as in Thecla, the neuration of the male not affected by the discal stigma. Cell balf as long as the wing, much narrowed apically ; course of the upper cross vein closing the cell oblique, arising from the first inferior subcostal nervure, as far beyond the origin of the latter, as that beyond the base of the second superior nervule, the lower cross vein closing the cell obsolete; first subcostal and median uervules arising a littie beyond the middle of the cell. Hind wings with the whole lower half produced, the inner being much longer than the costal margin, the lower median nervules produced to filiform tails of greatly unequal length, the inner margin excised apically, the anal angle faintly lobed. Subcostal and median nervures first branching at equal distances from the base.

All the legs short but pretty stont, the fore tibiae as long as the fore tarsi, and only a little shorter than the hind tibiae, and about a third shorter than the hind tarsi, which are a sixth longer than the hind tibiae; fore tarsal joints of the male obscure, the last bluntly rounded at tip and furuished with a pair of spines differing in no way from the others, except in being directed at right angles downward. Hind tarsal joints clothed beneath incouspicuously with short and fine, recumbent spines; first joint equalling all the others. Claws exceedingly small and delicate, bent in the middle; paronychia slender, as long as the claw.

The early stages are known only by the illustrations given in Boisduval and LeConte's Iconograply, which sbow nothing generically distinctive.

The genus is fairly well represented in the tropies of America, three or four speeies beiug known in North America, one of them inlabiting our southern states; some of the Central American forms extend to the Amazons, Guiana and Venezucla, and probably there are others in northern South America. Their transformations are known only through the United States species, mentioned below.

## EUPSYCHE M-ALBUM.

Thecla m-album Boisd.-LeC., Lép. Amér. sept., 86-87, pl. 26, figs. 1-5 (1833);-French, Butt.east. U. S., 256-257 (1856) ;-Godm.-Salv., Biol. centr. amer., Lep., ii : 40 (1887).

Eupsyche m-album Scudd., Bull. Buff. soc. nat. se., iii: 112 (1876).

Thecla psyche Boisd.-LeC., Lép. Amer. sept., 88-89, pl. 27, fiǵs. 1-5 (1833).

Imago. Head with the face black, edged externally with white, tufted above with black scales; the eye uarrowly encircled behind with white. Antennae black, heavily annulated with white, excepting on the club which is black, the apex orange. Thorax
covered above with browu, having bluish and green reflections, and similar blue green scales, below with yellowish brown hairs; the legs more or less flecked and annulated with sordid white.

Wings above rich black brown, the disk more or less intensifled, supplanted by brilliant, glossy, dark blue with green reflections. Fore wings with the costal edge orange; in the male the blue disk is limited by a line which follows the upper margin of the cell, passes in a strongly rounded curve to the middle of the upper median nervule and then runs subparallel to the outer margin to the inner margin; it encloses a discal triangular spot of dead brown androconia at the outer limit of the cell, its apex below; in the female the blue disk is confined to patches in the lower half of the cell, at the base of the lower median and the basal half of the medio-submedian and internal interspaces. Hind wings: in the male, the blue disk is limited by a curving line which passes above the cell, encloses a little of the upper subcostal interspace and runs toward the lower median nervule in a curve, constautly approaching the outer margin; in the female it occupies scarcely less space; anal angle marked by a bright, dark orange spot, flecked to a certain extent with blue scales, especially on the upper inner surface, followed without by the black edging of the whole outer margin, and within, above, by a small white spot; tails black, white tipped; fringe of all the wings pale brown, becoming white in the lower half of the hind wings.

Beneath, uniform mouse-brown. Fore wings crossed by a straight, narrow, white stripe, more or less interrupted by the nervures, edged more or less faintly on the inner side with dark brown, and running from the costal margin to the middle of the lowest median nervule at right angles to the costal margin; nearly midway betweeu this and the outer margin, but parallel to the latter is a similar but very obscure and cloudy stripe, edged without, instead of within, by the dark brown, sometimes more or less obsolete. Hind wings with a similar, but if anything narrower, transverse, extramesial stripe, forming a very large, fine $W$ or reversed $M$, whence the name; in character it is in most respects similar to that of the fore wings, being interrupted by nervures, sometimes shifted slightly in position by them, but runs from the upper subcostal nervule in a nearly straight course to the lower median nervule, in the mediosubmedian interspaces forms the middle limbs of the $M$, and in the interspace below runs at right angles to its early course, crossing the middle of the costo-subcostal interspace as a short, sleuder, white bar, edged internally with black; midway betweeu the $M$-streak and outer border is another series of white bars, often obsolete in the upper half of the wing, generally disconnected, sometimes scattered to form a powdery line, and then more or less bluish in tint; it is only in the lower half of the wing that it becomes distinct, and here it takes a course subparallel to the gencral trend of the extra-mesial stripe and is distinctly followed exteriorly with black; these two parts are separated by a large and brilliant, lighter or deeper orange, round spot in the lowest median interspace, a spot which is ordinarily accompanied at its exterior base by a small black spot, and is edged above with black; anal angle occupied by a deep black spot, followed above, interiorly, by a small white spot, exteriorly by a larger orange spot; and in the apical portion of the medio-submedian interspace a black spot, heavily powdered with blue, sometimes so that the blue almost supplants the black; this spot is edged above with white before meeting the tongue of the orange spot of the interspace below. Expanse of wings, $36-38 \mathrm{~mm}$.

Caterpillar. Last stage. Head black. Body slightly pubescent, of a pale green with a yellowish tinge, a dorsal stripe and seven oblique, lateral streaks of a dull green, a stigmatal yellow stripe, slightly shaded with dull green above. Length, 18 mm . (Boisduval and LeConte.)

Chrysalis. Gray brown, with the front part of the body and the wing cases pale, slightly greeuish gray. Length, 11 mm . ; height, 5 mm . (Boisduval and LeConte.)

This pretty butterfly occurs in the southern half of the United States, east of the Great Plains, and extends southward also into Mexico and

Guatemala, Costa Rica and Venezuela ; it has occasionally been found in the sonthern portion of the northern half of the United States, being reported from New Jersey, Pennsylvania and Ohio.

Although the early stages of this butterfly were studied and figured in the last century by Abbot, and published by Boisduval and LeConte more than half a century ago, we have not yet any proper account of the history of the species. Abbot's notes, however, assure us that it winters in the chrysalis and is more than single brooded. He reared specimens September 5 and February 20, the former after sixteen days in the chrysalis, the latter from one that changed later than August. According to him, also, the caterpillar feeds on Astragalus canadensis and A. glaber, as well as on different oaks of which he specially mentions "black jack oak," which is perhaps Q. catesbyi. The only other published date of capture is one by Aaron who took it June 11 at Atlantic City, New Jersey. It is, therefore, very probably triple brooded in the south.

## ATLIDES HÜBNER.

Atlides Hübn., Verz. bek. schmett., 80 (1816); Theela pars Auctorum. -Eutl., Cat. Fabr. Lep., 197 (1869).

Imago. Head not large, compact, the front slightly narrower below than above, above as broad as the eye on a face view. Eyes as in Eupsyche. Antennae much less than half as long as the fore wing, considerably longer than the abdomen, moderately stont, increasing in size from the middle outward, separated at base by nearly the width of the lower part of the front, composed of about thirty-fire joints, the club hardly separable from the stalk, increasing with the ntmost regularity to the middle of the outer half, beyond which there are about a dozen equal joints, less than twice as stont as the stalk, and ouly a little broader than long, aud then a couple of joints serve to gire the cluba bluntly rounded tip; the longest joints of the stalk are barely three times as long as broad. Palpi very small indeed, the last joint, if appressed to the head, not reaching the base of the antennae by its own length: only moderately slender and half as long as the middle joint.
Fore wings shaped as in Thecla but with a relatively longer inner margin, the nemration not affected by the exceedingly large discal stigma of the male, the cell considerably less than half as long as the wing, truncate at tip where it is harclly more than two-thirds its median width, the first superior subcostal nervule arising before the middle of the cell, the cell closed by feeble cross veins. Hind wings shaped much as in Eupsyche, with a larger anal lobe and preapical excision. Subcostal forking sooner than the median nervare.
Thorax large and massire. Legs pretty stout and very heavily clothed, the fore tarsi of male about a third shorter than the fore tibiae, scarcely more than half as long as the hind tarsi or the hind tibiae, which are about equal; fore tarsi of male faintly jointed, densely clothed with spines beneath like the others, the apical three or four very faintly arcuate, but not otherwise differing from the ordinary spines; first joint of hind tarsi fully as long as the three succeeding joints together, the apical pair of inferior spines of each joint slightly larger than the others. Claws exceedingly small, fine and strongly curved; paronychia forming a large, inferior, fringed hood concealing the basal half of the look.

The early stages are known only througli the illustrations of Boisduval and LeConte Which show nothing generically distinctive with certainty.

This group comprises the largest of our Theelidi and reaches its highest development in the Ameriean tropies. Six or eight speeies are found in Mexieo and Central America and some of them, as well as others, in the northern part of South America. A single one of them, described below, extends its range into the southern United States.

Their transformations are unknown exeept for the rude illustrations of our own species given by Boisduval and LeConte.

## ATLIDES HALESUS.

Papilio halesus Cram. Pap., exot., ii 3-4, pl. 98, figs. B, C (1779).

Thecla halesus Boisd.-LeC., Lép. Amér. sept., 83-85, pl. 25, figs. 1-5 (1833);-Freneh, Butt. east. U.S., 2כัॅ-256 (1886) ;-Godm.-Salv., Biol. eentr. am., Lep. rhop., ii : 18-19 (1887).

Attides halesus Butl., Cat. Fabr. Lep., 197 (1869).

Atlides dolichos Hübn., Zutr. exot. schmett., ii: 9, figs. 219-220 (1823).

Thectajuanita Scudd., Proc. Bost. soe. nat. hist., xi : 435゙-436 (1868).

Imago. Head black; a circular pearly white spot between the antennae, another just behind the summit of the eyes, a long and slender one in front of, and another behind the eyes; base and centre of the palpi white. Antennae black, the tip of the club brown; a trausverse plume of mingled black and white hairs on the vertex, bebind which is a collar of shorter white hairs. Thorax and abdomen well sprinkled above with bright blue scales on a brownish ground; thorax beneath black; a white dot on the sides at the base of either wing; legs black with occasional white scales. Abdomen beneath orange.

Wings above blackish brown; fore wings profusely suffised with bright blue (steel blne by reflected light) on the basal half, especially along the middle of the wing, but not between the divarications of the median nervure; fringe black, tipped with gray. Hind wings somewhat suffused with bright blue, especially along tbe area occupied by the median nervure and its divarications; there are two long tails: the upper is the extension of the middle median nervule, the lower, which is twice as long as the other, is the continnation of the lower median nervule; the interual area is slightly excised near the extremity and the portion beyond curved sharply over and beneath, at fully a right angle to the general plane of the wing; on the lower half of the outer margin of the wing are three spots, made of yellowish-brassy, greenish-brassy and bluishbrassy scales; that in the internal area is longitudinally oval, that between the mellian and submedian nervores transversely oval, and that between the tails transversely linear and least variable in coloration; the middle spot is also surmonnted by a number of inconspicnous deep tawny scales; on the internal area there is another similar but irregularly sbaped spot within but close to the outer one; internal area with long blnish gray hairs; fringe, as far as the longer tail, black, tipped with gray; beyond, white at extreme base; the outer parts black; wholly black beyond the spot on the anal angle.

Beneath, glossy grayish brown, lightest in tint toward the apices of the wings ; cxtreme base of the fore wings velvety black with a longitudinally oblong-ovate, bright, very deep orange red spot at the base of the costal area, but scarcely reaching the edge of the wing. Extreme base of the hind wings velvety black with two bright, rery deep orange-red spots: one circular, similarly situated to that on the fore wings, the other longitudinally oval, in the internal area; there is a transverse curving submarginal row of very bright, brassy-green, transversely ovate spots bordered with black, extending from the middle median nerrnle to the internal border; there is a row of marginal spots generally similar to those of the upper surface; the deep, tawny spots are, however, fonnd in all the interspaces, are more conspicnous and between them and the submarginal row mentioned, is a row of transversely linear spots similar to the marginal spots. Expanse of wings, 51 mm . ; length of lower tail, 18 mm .

Caterpillar. Last stage. Head testaceous yellow red. Body green, slightly pubescent; a slight dorsal stripe and nine oblique lateral bands of dull green, and a marginal stripe of greenish yellow at the substigmatal fold; thoracic legs of the color of the head. Length, 24 mm . (Boisduval and LeConte).

Chrysalis. Reddish, pointed with brown. Length, 18 mm. ; height, 7 mm . (Boisduval and LeConte).

This fine butterfly, called the Great purple hair-streak by Abbot, is found in the southern half of the United States from ocean to ocean, and extends also into Mexico as far as Yucatan and perhaps into Costa Rica. Its northern boundaries are by no means well known, but though it has been found in Nevada according to Edwards (presumably southern Nevada), it does not appear to range so far north as Eupsyche m-album, the northernmost locality east of the Rocky Mountains being Illinois.

The caterpillar is said by Abbot to feed on Quercus phellos and Q. cinerea. Its seasons are very probably the same as those of Eupsyche m -album, as it is found flying at the time of peach blossoms in Florida and was raised by Abbot early in September from a chrysalis whose period was seventeen days.

## TRIBE LYCAENIDI.

NOMIADES HÜBNER.

## NOMIADES LYGDAMUS.

Polyommatus lygdamus Donbl., Entom., 200-211 (1842).

Glaucopsyche lygdamus Scudd., Syst. rev. Amer. butt., 33-34 (1872).

Nomiades lygdamus Scudd., Bull. Buff. soc. nat. sc., iii: 117 (1876) ; Can. ent., viii: 23
(1876).

Lycaena lygdamus Streck., Lep. Rhop.Het., 84 (1874);-French, Butt. east. U. S., 284-285 (1886).

Lycaena lygdamas Edw., Butt. N. A., i: Lycaena 1, figs. $\overline{0}-7$ (1869).

[^5]spot in the middle of the cell; its outer limit is marked by a black line or bar and there is a row, arcuate in the fore wing, sinuons in the hind wing, of tolerably large, round black spots, one in each of the interspaces, crossing the middle of the outer half of the wing; all these spots are encircled with white; the outer edge is fincly marked with a black brown thread preceded by a similar white one; the arcuate row of extramesial spots of the fore wing is subparallel to the outer border, the uppermost spot in the lowest superior subcostal interspace retreating somewhat from it; on the hind wings the spots of this series are usually more perfectly circular than the corresponding spots of the fore wing, often slightly smaller than there, excepting that in the medio-submedian interspace which is donble or when blended transverse; the two spots of the costo-subcostal and subcostal interspaces are removed inward further from the next portion of the series, which consists of a strongly arcuate row of four spots in the next succeeding interspaces as far as the medio-submedian; the spot in the latter again approaches the margin, while the small spot below it again recedes from it; in addition there is on the hind wings an entirely similar spot in the costo-subcostal interspace, above and a little outside of the spot in the centre of the cell. Expanse of wiugs J, 26-36 mm. ; f, 38 mm .

The large size of the extra-mesial spots of the hind wings, where with their white edging they completely fill the interspaces as far as the scaly covering of the nervnles, is one of the characteristic features of this species.

The range of this silvery blue butterfly is still imperfectly known. It certainly is found in the states bordering the Atlantic from the upper waters of the Susquehanna to Georgia, probably following the Appalachiana. It also occurs beyond the Atlantic states, but only in the north, reaching westward to Obio, Michigan and Wisconsin.

In Georgia, according to Abbot, it flies throughont March and occurs in pine woods, flying very swiftly. In West Virginia it appears early in April, according to Mr. Edwards, and flies throughout that month, as I have good specimens taken there at the end of April. Edwards says it is rare, "not more than half a dozen being seen in a season," and is usually found "in the garden or about houses." Nothing more of its history is known.

## RUSTICUS HÜBNER.

## RUSTICUS STRIATUS.

## Lycaena striata Edw., Field and forest, iii : 88 (1877).

#### Abstract

Imago. "Male. Expands 1 inch. Upper side dull pruinose blue, the secondaries of a gray shade; the wings delicate, allowing much of the marking of under side to be discovered above; primaries edged by an illy defined, fuscous line, a little expanded towards apex, secondaries by a clear, black line; fringes of primaries fuscous next to the marginal edge, white outside, of secondaries pure white. Under side gray white; both wings banded from base nearly to margin with pale fuscous; on secondaries these bands are macular; on primaries nearly regular, but the bands do not pass the lower branch of median; hind margins edged by a common series of pale fuscous, crenated spots, each enclosing a small, concolored, rounded spot, except next anal angle, where are two round, velvet black spots, the onter one largest; these are faintly margined by yellow and their surfaces a little sprinkled with brilliant metallic blue scales, mostly arranged along the edges. "Female. Expands .95 inch. The costal and bind margin and base of primaries pale fuscous, the disk whitish, and a blue tint over busal area; on the disk appear fonr or five spots caused by the transparency of the wing ; secondarics had the costal mar-

gin largely pale fuscous and the remainder of the wing nearly pure white, excepting along the hind margin, where there is a fuscous band euclosing rounded, white spots each of which itself encloses a fuscous spot on the marginal side; the inner spot on lower mediau interspace is blackish, under side as on the male."

This butterfly originally described as above by Edwards from specimens obtained at Sau Antonio, Texas, by Boll, is stated by him to have occurred also at Racine, Wisc. (Hoy). Nothing more is knowu of it ; it presumably belongs to Rusticus.

## TRIBE CHRYSOPHANIDI.

## EPIDEMIA SCUDDER.

## EPIDEMIA DORCAS.

Lgcaena dorcas Kirb., Faun. bor. amer., iv: 290, pl. 4, fir. 1 (1837).

Epidemia dorcas Scudd., Bull. Buff. soc. nat. se., ili : 128 (1876).

Polyommatus anthelle Boisd. MSS., Donbl., List. Lep. Brit. Mus., ii : ${ }^{\text {ā }}$ (1847).

Polyommatus epixanthe pars Möschl., Stett. ent. zeit., xxxi: 114-115 (1870).

Imago. IIead in front snow-white with a broad, median, black-brown stripe ruuaing dowa between the antennae almost to the base; above tufted with jet black, olivaceous and fulvous scales, the first in greatest abundance; a snow-white fringe behind the eyc. Palpi white, excepting the apex of the middle joint and all of the apical joint bit an inferior line and the extreme tip, which are blackish brown; the inferior fringe of mingled black and white hairs. Antennae black-brown, with moderately narrow, basal, white aunulations on all the joints; the club itself velvety black above, sordid white beneath at the base, luteo-fulvous on the naked portions. Thorax covered with glossy black hairs, with intermingled tarmy hairs, especially around the base of the wings; beneath covered with pure white scales aud sordid bluish white hairs; the legs white, the terminal tarsal joints annulate with brown; the spines dark castaneous.

Upper surface of the wings having the disk either bronze brown with a violaceous reflection, most distinct at the extreme base ( $\delta$ ), or dark grisly brown with scarcely perceptible violaceous reflections (\%). The fore wings are marked by a blackish brown spot just beyond the middle of the cell, a black bar marking its termination, a small blackish brown spot in the medio-submedian interspace, just below the first divarication of the median nervure, and a transverse, sinuous series of spots crossing the middle of the onter half of the wing, obscure brown, circular and small in the male, quadrate and nearly filling the interspaces, as well as followed by narrower or broader, dull orange rays in the female, iu all the interspaces between the lowest superior subcostal and the medio-submedian inclusive; the series is more irregular and sinuous in the female thau in the male, and in the latter is nearly parallel to the outer margin; the outer border broadly margined with dark brown, as far as midway between this extra-mesial series of spots and the margin itself; in the male the spots in and at the extremity of the cell are a little more distinct thau the others. Hind vings with a narrow, blackish bar closing the cell, aud a little within the outer half of the wing a series of spots, whose relative importance in the two sexes is as on the fore wings, is found ia the same interspaces as there; onter margin dark brown, not so dark as on the fore wiugs, and with no such distinct limitation, mergiug insensibly into the warmer tint of the disk; slight orange lunules are found, often subobsolete, in the medio-submedian and lower median interspaces, in the former more distinct and at the anal angle.

Beneath, nearly uniform, very pale orange buff; the hind wings, however, often grayer, sometimes pinkish in tone; the markiugs of the upper surface are fully re-
peated beueath, excepting the broad margin of the outside, which is indicated only by a series of dusky brown, interspaeial spots at its inuer limit, more obscure on the upper than on the lower half of the wing; neither do the spots differ in size or form in the two sexes, being larger and more distinct than those of the upper surface of the male, but round or oval, as in that sex above; there is in addition a minute black spot in the cell, midway between the extra-mesial spot and the base. Hind wings traversed by two series of fine and rather faint, black or blackish brown spots, which appear as the point of vague sagittate or lumulate spots pointed toward the outer margin, one extra-mesial, the other intra-mesial, and corresponding in position to the spots of the upper surface; these are often subobsolete; there is a submarginal series of faint, pale orange lunules, much more distinct on the lower than on the upper half of the wing, elear and well marked only next the anal angle; they generally take the form of thin, sagittate spots, and are deepest in color along their middle line, fading to yellow outwardly; they differ from the corresponding spots in the allied E. epixanthe in their sharp angulation. Expanse of wings $\delta, 25 \mathrm{~mm} . ; \quad$;, 29 mm .

This butterfly is found only in the Dominion of Canada, where it ranges from the southern coast of Labrador on the east to Lake Winnipeg and the Saskatehewan on the west, and even, aecording to Edwards, as far as Kodiak, Alaska. Geddes does not appear to have taken it in his collections west of Manitoba, so that it is hardly probable that jt anywhere approaches near the southern borders of the Dominion, unless it does so about Nepigon, where it has not yet been found.

Couper found it in southern Labrador in Jnly, but that is the only indication of its seasons whieh we have. In all probability it is single brooded. Nothing is known of the early stages.

## PAPILIONIDAE.

 SUBFAMILY PIERINAE. TRIBE RHODOCERIDI. CALLIDRYAS BOISDUVAL.
## CALLIDRYAS SENNAE.

Papilio sennae Linn., Syst. nat., ed. x, i: 470 (1758).
Callidryas sennae Butl., Lep. exot., 59, pl. 23, tigs. 1-4 (1871) ;-Scudd., Proc. Bost. soc. nat. hist., xvii:20s (1870) ;-Edw., Trans. Amer. ent. soc., ix:11-12 (1881);-French, Butt. east. U. S., 120-124 (1886).

Phoebis eubule Hübn., Samml. exot. schmett., ii (1822-26).
[Not Papilio eubnte Linn.]

[^6]brown, paler toward the base, flecked above with pale blue scales, the apical joint wholly luteons.

Body covered above with pallid and pale greenish hairs, below with pale yellow scales and hairs, the legs pale luteous; the femora tinged with yellow, the tarsi slightly embrowned; the spines and claws concolorons, the tips of the latter brown.

Wings above pale lemon yellow, in the male uniform, excepting for the mealy edging, which is narrow; twice as wide on the fore wings as on the hind, with the interior border parallel to the margin on the hind wings, crenulate on the fore wings; in the female varying in depth from a sordid, greeuish white, through a dull, rather sordid, lemon yellow (and then with very slight markings) to a dceper greenish yellow, very faintly tinged, especially on the hind wings with orange. Fore wings of female edged with clark brown, having a slightly ruddy tint, varying in depth in different individuals, in the most marked running as a narrow borler, beginning on the costal margin, a little way beyond the cell, expanding as it goes until it reaches the apex, when the width is in general constant and about half an interspace, excepting that it is considerably crenulated, and, when not fullest developed, is seen to be composed of subconflnent, transverse, oval spots seated on the nervire tips; there is also a large, often double, roundish spot of the same brown, at the extremity of the cell, when lonble, the npper spot smaller than the lower, enlivened by a few clnstered orange and yellow scales, following the transverse veins; there is also a bent series of powlery fleckings in all the subcostal and median interspaces, in the subcosto-median interspace removed nearly halfway to the cell; in those of the others which open upon the outer border, at a distance of about an interspace and a half from that border; in those which open on the costal border, nearer that border; this series of fleckings is sometimes entirely ohsolete, sometimes developed so as to form oblique or broken sagittate spots in the interspaces. Hind wings of the female narrowly margined with long, oval, transverse, brownish spots at the tips of the nervules, separated from the extreme margin only by a slender orange line.

Beneath pale, sometimes very pale, greenish yellow, often with an orange tint. Fore wings with the onter margin rather broadly snffused with pinkish orange; the submarginal markings of the upper wing are repeated with greater distinctness and heaviness, but still as powclery markings, generally in the form of bars or lunules of orange ferruginons, flecked more or less, but never profusely, with black scales; besides this, the only marking is a spot, now almost inwariably double and much larger, at the extremity of the cell, the central portion generally silvery, but more or less obscured, sometimes entirely obscured, with orange ferruginous, and margined with black, surrombled more or less with orange ferrnginous; occasionally a third or fourth bit of silvery or orange scalcs is marked off from the main spot by the ferruginous surromndings iu the smaller portion of the spot, which lies within the cell. Hind wings crossed by four parallel, nearly straight series of slender interrupted fleckings, subparallel to the outer margin : the first consists of two or three dots of clustered, ferruginons scales at the united root of all the veins, the extreme basc of the costo-subcostal interspaces and in the costo-marginal interspace; the second crosses the wing obliquely at the first forking of the subcostal vein in a series of fleckings which run from the costal to the internal nervure, interropted to the greatest degree at the subcostal fork; the third crosses the wing at the tip of the cell and runs from the costal margin, just before the tip of the first upper subcostal nervule, to the middle of the submedian nervure, very slender and much interrapted, excepting at the extremity of the cell, where it usually forms a tolerably brond and continnous belt of powdery ferruginons scales, flecked with black, and euclosing at the extreme base of the subcosto-median interspace and beside it in the lower subcostal interspace, a pair of circular or oval, bright silver spots, each with a slender, blackish ferruginous annulas; the last transverse series of fleckings is similar to the extra-mesial series of the fore wings, and is less regular thau the others, formed mainly of four slender, powdery lunules in the median, subcostomedian and lower subcostal interspaces, in the upper median nearer the margin than in the other interspaces, where they are nearer the extremity of the cell than the outer
margin; the outer margin itself is usually margined with a pink orange flush, but not so broadly nor so constantly as in the fore wing, and at the extremity of the nervules are of ten seen black points. Expanse of wings, $60-66 \mathrm{~mm}$.

1. Last stage. Head greeu. Body green, profusely covered with small, but very distinct and elevated black tubercles; a bright yellow stigmatal stripe the whole length of the body bordered above by deeper green. Legs green. Before changing it becomes yellow and shining. Leugth, 47 mm . (after Sepp and Stoll).

Chrysalis. Uniform green, the antennae and a slender lateral line yellow, according to Sepp, the whole chrysalis sometimes violet, or according to Stoll', changing to violet before change, when and wheu only little white flecks appear on the abdomen. The frontal tubercle is stouter than in C. cubule and the mesonotal arch hardly so strong. Length, 32.5 mm . ; the same followiug the middle line of the body, 35.5 mm .; height in middle, 13.5 mm . (after Sepp and Stoll'). Sepp's figures are uqquestiouably the better.

This butterfly is an inhabitant of tropical America, mainland and island, and is not only found along our extreme southern coast, particularly in southern Florida, Texas and Arizona, but occasionally wanders up the Mississippi valley so as to have been taken as far north as southern Illinois. Edwards, in one of his catalogues, says it occurs occasionally in Nebraska; but as he afterwards transfers this statement to C. agarithe, it is probable that he formerly confounded the two species.

It is probably the caterpillar and chrysalis of this species which are figured by Stoll' and Sepp in the places indicated in the synonymy above. The caterpillar fceds upon different kinds of Cassia, and according to Sepp also on Hypericum baccifermm. Stoll' adds that it also feeds on species of Citrus, but this is improbable.* The chrysalis state lasts from eight to ten days. There are several broods annually, for Sepp says that the caterpillars may be found "en diverses époques de l'année."

## CALLIDRYAS PHILEA.

Papilio philea Linn., Syst. nat., ed. xii, : 764 (1767).
Callidryas philea Butl., Lep. exot., 92, pl. 35, figs. 1-1 (ts72);-Scudd., Proc. Bost. soe. nat. hist., xvii: 208 (1875); - Edr., Trans. Amer. eut. soc., ix : 13-1t (1881); French, Butt. east. U. S., 124 (1886).

Colias corday Hübn., verz. bek. schmett., 99 (1816).

Colias hersilia Hübn., Verz. bek. schmett., 99 (1816).
[Not Papilio hersilia Cramer.]

Imago. Head tufted above with pink tipped, dark greenish brown scales and hairs. Palpi above the same, but on the sicles wholly yellow or orange. Antennae dark brown with a castaneons tinge, the incisures and apical joint lighter, the stalk and base of club flecked with pale rosy scales. Body corered abore with yellow and greenish jellow hairs, beneath with yellow aud orange hairs and scales, the legs concolorous, the tarsi luteous becoming infnscated apically.

Above, fore wings either bright yellow with a greenish tinge, with a very broad and large, orange, sometimes rather pale orange, subquadrangular bar or patch crossing the

[^7][^8]cell beyond the middle at right angles to the costal margin; extending above half way hetween the cell and the margin, below about to the centre of the medio-submedian interspace, its exterior margin crossing the cell above about midway between the base of the first and of the second subcostal bervules and below just including the extreme base of the upper median interspace, the whole rather broader than the cell and rounded beneath; the apical half of the costal and the upper half of the outer margin marked in black, most distinctly at the middle of the interspaces, those on the lower half of the wing being marked apically in the same way; besides there is a very broall exterior mealy baud of raised scales, in the form of broad and very long lumules in the interspaces, separated apically ouly by the nermres, and extending to the depth of an interspace and a half in the lower half of the wing, as far as the cell above, even filling the whole of the upper subcostal interspaces and often present as a small patch in the apex of the cell itself ( $\left(\begin{array}{l}\text { ) ; or, sordid yellow often more or less pallid, sometimes with }\end{array}\right.$ an orange tinge especially toward the onter border, with the marginal markings of the other sex to form distinct, tolerably large, transverse, oval, blackish brown spots, confluent with a narrow band at the apex of the wing, besides having an extra-mesial series of smaller and more or less powdery spots in all the subcostal and median interspaces, near the middle of the apical two-thirds of each interspace, forming thus a tolerably sinuous series, bent strongls at aboutright angles at the apex by the spots in the upper subcostal interspaces; besides these an obscure similar spot at the lower extremity of the cell cut by the transverse nervure ( $\ddagger$ ). Ifind wings of the same coloras the fore wings, the outer margin with a very broad suffused blush of yellow orange ( $\delta$ ) or red orange ( $\%$ ) growing deeper in tone toward the outer margin, much broader (often covering half the wing) in the female than in the male and in both narrowing and fading above and below; it is accompanied in the female by tolerably large, transverse, oval, powdery, blackish spots barely before the margin seated on the nervules insteat of, as on the fore wings, in the interspaces. In the male there is a very narrow, uniform area of raised scales along the onter margin.

Beneath orange buff, heavily flecked in the female with ferruginons orange. Fore wings with the dark markings of the upper surface of the female repeated in both sexes in ferruginous with these variations: the marginal markings of the male are even less distinct than in the same sex above, often quite absent; and the spot at the end of the cell is generally larger, accompanled by another seated on the upper transverse vein and both more or less heavily pupiled with silvery. Hind wings crossed, more hearily in the female than in the male, by an extra-mesial series of very powdery ferruginous, slender lunules corresponding to the similar series of the fore wings, besides similar, transverse, powdery, ferruginons bars forming a subcontinnous, narrow, bent, $V$-shaped stripe near the base of the wing below the snbcostal nervure, accompanied by a bar edging interiorly the lower, onter margin of the cell and two small silvery ovals on either sile of the extreme base of the last subcostal nervule, set at right angles to each other (more distinctly in male than female) and edged with ferruginous. Expanse of wings, $80-98 \mathrm{~mm}$.

This Callidryas, like the preceding, is a tropical species, extending from Mexico to Bahia, but is apparently confined to the mainland and so invades the United States only at one point, so that, so far as known, it is only found constantly in Texas, but it, too, occasionally flies northward up the Mississippi valley and has been found even as far as northern Illinois (Evanston, Bontell) and Wisconsin (Racine, Hoy).

The early stages are quite unknown and no information is at hand regarding the history or seasons of the insect.

# ZERENE HÜBNER. 

Zerene IIibn., Verz. bek. schmett., 97 (1816); -Sculd., Proc. amer. acad. sc., x: 291 (187⿹勹).<br>Megonostoma Reak., Proc. ent. soc. Philad. ii: $3 \overline{5} 6$ (1563).

Imago. Head rather large, front quadrate, nearly flat, the lower half slighty projecting, slightly broader above than below, the upper part bent at an exceedingly broad angle with the lower, furnishing a somewhat depressed field for the antennal pits which are separated by their own width and reach behind the tine, carinate, erect edge of the broad and mesially tumid rertex. Eyes large, full, naked. Antennae about as long as the ablomen, composed of thirty-two joints, the last double, of which about nine form the very gradually increased, abruptly terminated, cylindrical club, which is about twice as broad as the stalk, with indistinguishable proximal limits, not tapering distally, the largest joints (except the double apical joint) kalf as broad again as long, the longest joints of the stalk nearly three times as long as broad. Palpi small, short, compressed, compactly clothed, the middle joint compressed, regularly arcuate, equal, fully fise times as long as broad, the last stout, oval, not much longer than the breadth of the middle joint.

Fore wings slightly falcate, the costal margin being well arched apically, the apex angular and the outer margin straight or even slightly excised above ; inner margin full in its basal half. Subcostal nervure with three branches, the last forked and originating nearer the second than that the first, the second arising at the tip of the cell; the latter less than half as long as the wing and about three times as long as broad. Hind wings as in Eurymus, though somewhat longer.

Legs rather slender, the fore legs of the female differing from those of the male only in their greater lengtb. Fore femora (comparisons with male only) as long as hind tibiae, more than half as long again as the fore tibiae, which equal the first joint of fore tarsi ; the first joint of fore tarsi equalling the rest together. Hind femora two-thirds the length of the tibia which is a fifth longer than the first tarsal joint; the latter longer than the next three joints together, the fifth as long as the third. Claws very delicate, compressed, elongate, slender, gently arcuate, strongly heeled, slightly divaricate, cleft nearly to the heel, very finely pointed. Paronychia simple, forming a moderately stout, triangular, tapering and pointed lobe, closely appressed to the claw, reaching but little beyond the cleft and united at hase beneath.

Egg. Fusiform, nearly three times as high as broad, largest a little below the middle, tapering more rapidly to the base which is about half as broad as the middle, than to the very slender, bluntly rounded top, with a considerable nnmber of slightly and equally raised vertical ribs.

Caterpillar at birth. Dermal appendages of the body Indian-club shaped or long wine-glass shaped, nearly twice as long as the sections on which they are seated, but not more than a third as long as the segments, arranged in the following series, one to a segment in each: a laterodorsal on the anterior section; a supralateral series, scarcely behind the middle of the segments; a suprastigmatal, scarcels before the middle of each segment; and an infrastigmatal series, two to a segment.

Mature caterpillar. Closely agreeing in general appearance with Eurymus, but with a smooth, lenticular, suprastigmatal disk on the second and third thoracic segment.

Chrysalis. Resembling that of Eurymus, but with the mesonotum less elevated, and the frontal process apparently more highly developed.

This is an American type of Rhodoceridi, reaching its highest development in the United States, where two species occur, one eastern and syngenic, the other western and antigenic, but several members are scattered
throughout Mexico and Central America and the northern parts of South America.

The butterflies are uniformly larger than the species of Eurymus, both groups being remarkably monotonous in this respeet, though not without variation, but the bordering of the fore wing presents that remarkable irregularity, by its recession in the median interspaces, at least in the male, which gives it the dog's head pattern occurring also frequently in the genera allied to Terias, such as Pyrisitia among those here described.

In their transformations, so far as wel know them, they seem to closely resemble Eurymus.

Papilio sesonia Stoll', Cram., Pap.exot. Suppl., 176-177 (1791);-Mart., Psyche, pl. 2, fig. 5,6 (1797).

Imago. Head covered above witl mingled pale brown, pink, palliu and black hairs and pink scales; in front with pink-tipped pale fellowish scales. Palpi mingled yellow and pink, the latter predominating, with a few black hairs. Antemae heavily clothed with pink scales, partially erect, the apex and whole under surface of the club olivaceo-luteous. Thorax covered above with pale yellowish green hairs, beueath with pale yellow and yellowish buff hairs; the femora pale pink interiorly, very pale yellowish greeu externally; the tibiae piuk above but yellowish beneath, as are the whole of the tarsi, thongh the latter are more or less tinged with pink above.

Wings above bright lemon yellow, sometimes suffused slightly, especially upon the hind wings and the outer half of the fore wings, with orange. Fore voings with the basal half above the cell, the basal third below it, black, heavily flecked with yellow seales and short yellow hairs ; a romil or transverse oval black spot, moderately large, at the extremity of the cell; the outcr border very broadly and generally very deeply covered with chocolate black, which is limited interiorly by a very irregular line, clear and distinct iu the male, powdery in the female; it is formed of three nearly equal divisions separated by the upper and lower median nervules; the upper third is strongly arcuate, runs from the costal margin to the upper median nervule, its convexity outward, so as to just cross to the base of the third superior subcostal nervule, and to terminate on the upper nedian nervule about as far beyond the cell as the width of the apex of the cell; the middle third crosses the median interspaces by at once transferring the outer limit halfway to the border of the wing, forming thus a deep quadrate excision of the marginal band which has a slight tooth baseward at the middle median neryule; the third portion varies in the two sexes; in both it traverses the medio-submedian interspace in a strong curve, convexity inward, running from the middle of the lower median nervule to a point on the submedian a little nearer the margin; below this in the male it runs obliquely to the middle of the inner margin; in the female it either contimes in its original course or shows the same markings as the male in a vague powdery form; the tips of the subcostal nervures as they strike the costal margin marked in white more or less extensively. Hind wings with a pair of pale, faint, round orange spots, one at the middle of the apex of the cell, the other heside it in the lowest subcostal interspace, due to the transparency of the
wing; besides this there are no other markings excepting that in the male there is a narrow marginal black band running from just above the upper subcostal nervule to the middle median nervure, its inner border crenulate, occasionally broken by the nervules and limited to a narrower space; in the females indicated only by some powdery streaks upon the nervule tips in the upper half of the wing and by three or four small powdery spots at more than an interspace's distance from the margin; at the extreme base of the costo-subcostal interspace in the male, extending as far as the first divarication of the subcostal, is a large, quadrate, dull orange patch of special scales.

Beneath, uniform yellow, slightly less greenish than above; hind wings a little darker than the fore wings, occasionally flushed with pink along the costal and outer margin, particularly on the hind wings, and also on the same along the under surface of the subcostal and submedian nervures in the basal third of the wing, and supplanting the color of the spots of the same wing, excepting the silvery portions. Forewings witha large, round, black spot, covering the apical margin of the cell with a large, circular, silvery pupil with somewhat irregular outline; the costal edge, the outer half of the costal margin and the outer margin narrowly edged with pink, sometimes interrupted by the nervures ; occasionally a few points of pink or brown may be seen at more thau an interspace's distance from the outer margin in the interspaces. Hind wings with a pair of circular silver spots, one covering the upper half of the cross-vein, uniting the subcostal and median interspaces at the tip of the cell; the other about one-third its size, resting on the outer subcostal nervule beside the former; each surrounded by a double ring of ferruginous, the inner broader, the space between the two more or less fiecked with ferruginous; a pre-marginal series of small ferruginous or pinkish ferruginous scales in all the interspaces, but sometimes obsolete, at about the distance of an interspace and a half from the outer border. Expanse of wings, §, $59-63 \mathrm{~mm}$.; $\%, 53-69 \mathrm{~mm}$.

The following descriptions of the early stages are by Mr. Edwards, with the usual modifications:
Egg. Fusiform, thick in middle, tapering to a small, rounded summit; marked by about eighteen longitudinal ribs, these being low, narrow, the spaces between flat and crossed by many fine ridges. Color yellow green.

Caterpillar. First stage. Head rounded, a little depressed at top; on the face many rounded tubercles, each with depressed black hair; color pale yellow brown. Body cylindrical, thickest anteriorly; on the ridges of the segments many black points, each with a short, black hair; among these are black tubercles, some with long hairs, but most with white, clubbed appendages, which form three longitudinal rows on either side, one appendage in the row to the segment; "these rows are subdorsal, upper and lower lateral"; color greenish white, with a tint of brown. Length, 2 mm .

Second stage. Head rounded, nearly same green as the body, tubercles and hairs more numerous than before. The ridges of the body thickly beset with black points; each with black hair; among these are small tubercles of same color, mostly on middle of each ridge, with longer hairs; along base a yellowish, narrow stripe, and over it, on the second and third thoracic segments, a rounded black process; another larva showed this stripe only near the close of the stage, and had not the black process; color yellow green. Length, 2.6 mm .?

Thivel stage. Head yellow green, more thickly covered with small tubercles, scattered among which are others, larger. Color of body yellow green, with yellowish basal band; the processes on the thoracic segments as before, shining, black. Length, 5.3 mm .

Fourth stage. Head yellow green, a little lighter than body. Color of body yellow green, the band greenish white; the two processes on the thoracic segments present; on dorsum of the first thoracic and following segments are very small, black, rounded processes in cross line, and equidistant, placed on the second section of each segment; these are very variable in number; one larwa had four on the first thoracic and two each on the other thoracic segments, no others; another had three on the first thoracic, one on one side, two on the other, six on the second, two on the third thoracic seg-
ment, and these last were larger than any others; six seems to be the full number ou a segment, and they vary from that to oue, present on some segments, and lackiug ou others, with no apparent regularity; so also the number of lateral processes differs much; one had these on all segments except the first thoracic, first, fifth and uinth abdominal segments, as the stage progresses a yellow stain appears on the baud of each segment, aud at last is often orauge tinted. Leugth, $8-9.5 \mathrm{~mm}$.

Fifth stage. Head round, slightly depressed at top with many fue black points, each with short black hair; color yellow green. Body cylindrical, of nearly creu thickness from the second thoracic to seventh abdominal segments, thickly covered with smal black tubercles, each of which gives a short black hair; color yellow green, light or dark; aloug base a yellow white band, with a dash of orange on each segment, and sometimes the orange is nearly continuous; over the band, on the second and third thoracic segments, a large, vitreous, black, rounded process, from the top of which comes a small hair, and around the base is a ring of black points; some larvae have additional processes of same character on the succeeding segments; but there is much variation; occasionally all are large as on the secoud thoracic segment, usually they are much smaller; iu one example they diminish regularly ou the abdominal segments; on dorsum of one or many segments are small black processes on the secoud ridge, varying from six to one, and oftel wauting; the same ridge is covered by a black band, sometimes present ou every segment, sometimes only on the two or three anterior ones, with broken lines ou dorsum or sides of the succeeding ones, frequently, bowever, wanting; in many examples the first ridge of every segment is bright yellow, and the complete series of black and yellow bands is often present; but others have the yellow bauds broken up on middle and last segments, or lack them on these segments; others have a yellow line instead of band; and often there is no trace of yellow anywhere; some larrae, therefore, are wholly green, some green with yellow bands, some with black bands and no yellow, but more have both black aud yellow, witl variation as to extent of either; the black bands appear in the fifth stage, in examples which showed no trace of them in previous stage, and some larvae wholly green to end of fourth stage, at the moult took on all the bands; under side, legs and prolegs pale green. Length, $15-19 \mathrm{~mm}$.

There was much change in the markings at the previons moult, but still more at this. Some which had been wholly green at this monlt discover cross bands of black and yellow, one or both, and there was much variation in the extent of these bands.

Chrysalis. Shape of eurydice, compressed laterally, the thorax on ventral side prominent, risiug to a narrow ridge; the abdomen tapering, couical, the mesouotum low, rounded, with a slight carina, followed by a shallow excavation, the head case produced to a poiut, a little curved up, with a regular slope ou both dorsal aud veutral sides, angular laterally; color bluish green over whole dorsal side, below, the abdomen yellow greeu; the wing and head cases dusky greeu, on the under side a brown crescent, on dorsum two rows of black dots from mesonotum to eighth abdominal segment, one to each segment, and a small black spot on either side abdomen; the whole surface except wings dotted or finely streaked with whitish. Length, 20 mm ; breadth at mesonotum and on abdomen, 4.6 mm . ; greatest depth, 6 mm .

Another example gave same dimensions; the dorsum yellow green, ventral side of abdomen more yellow; a brown patch on muder side of head case.

An abundant species of the southern and especially the southwestern states, extending from the Atlantic to the Pacific, and reaching down into Mexico and Guatemala, and found as well on the larger West India islands -Cuba, Jamaica and St. Domingo-it has been reported as far north as Kansas, Wisconsin, southern Ontario and Pennsylvania, but does not nsually extend so far north in the east as it does in the central portion of the continent.

Notwithstanding its abundance, very little is known of its history or seasons, beyoud what Boisdusal and LeConte stated fifty years ago, and its carly stages have only very recently been fully described by Edwards. According to Boisduval and LeConte, it appears first on the wing in May, re:ppears again for the entire summer and a part of the autumn, flies in clover fields, but is found in the pine woods of the south, and feeds in the caterpillar state on different kinds of Glycine and Trifolium, as well as, according to Abbot, Dysodia chrysanthemoides, one of the Compositae.

Abbot, who called this the clonded yellow butterfly, says it "contimues to breed all the summer and autumn, is most common in the pine woods, and often settles, several together, to suck the moist places in roads and other places." He bred the butterfly May 2, after thirteen days in the chrysalis.

Elwards states that the eggs and young larvae were received by him from western Missouri August 2, caterpillars of all stages August 11, eggs and young caterpillars again on August 26 and October 8. Mr. Edwards found the duration of the egg in West Virginia about four days; of the successive larval stages from three to five days, the last a day longer, and the chrysalis from seven to ten days. The food plant in Missouri is stated by him to be Amorpha fruticosa, and in California, A. californica.

According to Rowley, the buttertlies are found during every month from April to November, and show a seasonal dimorphism in the presence or ${ }^{-}$ alsence of a rosy pink suffision on the under surface in special areas. He writes thens to Mr. Edwards:-
"The females with red under the wings do not occur' at all in the early smmmer broods. I took scores of butterflies this season in late $A_{\text {pril }}$, all through May, June and July, and discovered not a streak on one of them. The first examples with red were taken in August. In September they were more numerons, while nearly every female of late October aml Nuvember were either heavily streaked or solidly red below. I have yet to see a red under wing of earlier date than August. The feature is surely a seasonal one." (Can. ent., xx:24.)

## PYRISITIA BUTLER.

1'yrisitia Butl., Cist. ent., i:35, $\#(18: 0)$. Terias pars Auctorum.

[^9]very strongly compressed, the basal joint arcuate and pretty long, appressed to the head; the middle joint broad oval, not more than half as long again as broad; the third minute.

Fore wings rather long, with a strongly archef costal margin, a straight outer margin at right angles to the onter part of the costa and straight, long inner margin with rounded angle, the whole wing much more than half as long again as broat, the extremities of the costal and inner margins parallel. Costal nervore terminating a little beyond the cell, which is about half as long as the wing; subcostal nervure with three equidistant and not very distant superior branches, the second arising from the tip of the cell, the thisl forked. Hind wings lather long, rounded oval, with a broad, angular lobe at the extremity of the middle median nervale. No precostal nervare; vein closing the cell striking the last subcostal nervure a very little further from its origin than the last median from its base.

Legs very slender and delicate, not long. Fore femora in the male nearly half as long again as the hinc femora, nearly twice as long as the fore tibiac, which are scarcely longer than the first joint of the tarsi, and only half as long as the whole tarsus. Hind tibiae loalf as long again as the fore tibiae, a little longer than the first tarsal joint, which equals the three succeeding joints, the fifth joint being as long as the thirc. Spines very fine and crowded. Claws exceedingly small and delicate, no longer than the width of the last joint, and slender, deeply cleft and strongly arcuate. Paronychia simple, forming a large, oval, pilone, inferior, lateral flap, as long as the claws, and nearly half as broad as long.

This American type of Rhodoceridi is composed of a moderate number of species, whose home is in subtropical and tropical North America, occurring in South America only in the northermmost parts. Little or nothing is known of their history; the present species is the only one occurring in the United States.

## PYRISITIA MEXICANA.

| Terias mexicuna Boist., Spec. gén. Lép., <br>  U. S., 137-138, fig. 34 (1886). <br> Abae is mexicana Gey., Hübı., Zutr. exot. |

schmett., v: 29-30, figs. 917, 918 (1837).
Terias boisduvaliana Feld., Reise Novara, 200 (1865̄).
Abae is mexicana, Gey., Hübı., Zutr, exot.
Imago. Head covered with pink brown erect scales and hairs; palpi the same but with a greater or less number of pale yellow scales interminglerl, especially at the base; antennae brown above, white beneath, at the sides annnlate with white, the naked portion of the club ferruginons, the extreme tip dull luteous. Thorax corered above with bluish white hairs, below with yellow hairs; legs pale yellow, growing luteous toward the extremity.

Wings above white with a greenish tinge, heavily marked on the outer border with blackish brown. Fore wings having the costal edge marked with white at the tips of the subcostal nervules; the division between the light and dark portions of the wing is marked by a very irregular line, more irregular in the male than in the female; it starts from a little beyond the middle of the costal margin, runs in an oblique course to a little before the middle of the upper median nervule, then follows this nervule halfway or more than halfway to the margin, turns at nearly right angles, following the margin across the upper median and sometimes the lower median interspace, returns to its former distance from the margin by abruptly turning and following either the upper median ( $(\delta)$ or the lower median ( $\%$ ) nervule, crosses the medio-snbmedian interspace transversely and then rms sharply ontward, the base extending in a slender tongue a short ( $f$ ) or a great ( $(\delta)$ distance; extreme base of the inner margin flecked with brown, especially in the male. On the hind wings the outer bordering is distinc
and sharply defined in the wale, generally indistinct, subobsolete or powdered in the female ; in both it is narrow and is very irregular in its distribution, according to individuals, but in the males it is twice as broad in the lower subcostal as in the upper subcostal interspace; the upper third of the wing, limited by the lowest subcostal nervule, is tinget with orange yellow in the male, while in the female the whole wing is more or tess tinged faintly with greenish yellow.

Bencath: Fore rings pallid, more or less tinged with yellow on the basal third, particularly in the female, and flecked with ferruginous at the apex especially next the margins; a minute, black or clark brown spot at the upper extremity of the cell. Find uings pale yellow, more or less heavily but generally very lightly and delicately flecked with ferruginons in scattered dots or short transverse threads, which show a tendency to cluster into minute, regularly distributed spots along the basal latf of the costal margin and in a straight, transwerse streak which runs from close to the tip of the middle subcostal nervule to just within the extremity of the internal nervure, broken in the median interspaces; along the outer edge of this line the ferruginons dots and threads appear to clnster and to become more and more scattered as they outwardly depart from it; in addition to which there is usually a small ferruginous spot in the midulle of the median interspaces; occasionally the whole wing is decidedty tinged with brownish ferruginous by the multiplicity of these markings, but the relative distribution still remains the same; there is also at the upper outer extremity of the cell a minute black spot. Expanse of wings, $\delta, 38-44 \mathrm{~mm}$.; ㅇ, 42-46 mm.

As becomes its name, Mexico is the proper home of this species, but it inhabits also a considerable territory in the southwestern United States, being found throughout most of Texas, Arizona and southern California, and east of it even extending occasionally northward not only into Kansaz and Nebraska, but even into Iowa, Illinois and Wisconsin, and it has once been found in an extreme southwestern point in Ontario, -Point Pelee (Saunders).

Nothing whatever is known of its early history and no one has made any record of its seasons.

## NATHALIS BOISDUVAL.

Nathalis Boisd., Spee. gén. Lép., i: 589 (I836).
Imago. Head moderately hroad, especially abore; front half as broad again as high, a little broader above than below, scarcely at all tumid, rery uniform; vertex rery broad posteriorly, somewhat tumid with a sharp and rather deep, transverse sulcation just behind the antennae. Eyes small, not full, naked. Antennae considerably shorter than the abdomen, widely separated, composed of about thirty-three joints, of which twelre or thirteen form the ovate flattened club which is a little more than twice as long as broad, is very broadly rounded apically, increases regularly on the basal half, and whose broaclest joints are four times as broad as long or as the stalk, the longest joints of the stalk about three times as long as broad. Palpi long and rery slender, the basal aud middle joints of about equal lengtl, the apical joint rere short.

Fore wings long, nearly twice as long as broad, regular, the apex well rounded; costal margin gently arcuate to near the tip, one-fourth longer than the inner margin, the outer margin gently conrex. Costal nervure longer than the cell; subcostal nervure with three equidistant and distant, superior, simple branches, the middle arising from the apex of the cell, which is about half as long as the wing. Hind wings elongate, well rounded, long in the subcostal region, half as long again as broad. No precostal fein; vein closing the cell striking the last subcostal ant median nervules at equal distances from their basc.

Legs very slender and delicate. Fore femora (males only examined) nearly a fourth longer than the hind femora, a little longer than the fore tibiae; the latter five-sevenths the length of the fore tarsi, or of the bind tibiae; first joint of fore tarsi as long as the next three together, the fifth as long as the third. Hind tibiae fully as long as the first two tarsal joints, the basal joint barely exceeding the next two together, all the tarsi covered with slender spines. Claws exceedingly delicate, elongated, deeply bifid, gently arcuate. Paronychia simple, formed of a single, slight, slender, triangular lobe not a third as long as the claw and appressed to it.

It is doubtful if this neat little genus of American Rholoceridi, recognized more than fifty years ago, contains more than a single species or two. Yet it is found near the back bone of the continent from Nissouri to Venezuela and is also found in at least the larger West India islands, though not known even in southernmost Florida. It is the emallest of Rhodoceridi.

Nothing is publicly known of the early stages, but Mr. Edwards has reared it (Can. ent., xx: 157).

## NATHALIS IOLE.

Nathalis inte Boisd., Spec. gen. Lép., i:589090 (1836) ;-Reak., I'roc. ent. soc. Philad., vi : 134-135 (1se6);-French, Butt. east. U. S., 116117, fis. 31 (1886) ;-Cock., Can. ent., xx: 156157 (1888).

Nathalis felicia Poey, Mem. hist. nat.

Cuba., 443-444, pl. 18, figs. 18-21 (1851).
Nathalis irene Fitch, Rep. ins. N. Y., iii: 167-168 (1859).
? Nathalis luteolus Reak., Proc. ent. soc. Puilad., ii : 350-351 (1864).

Imago. Head covered with mingled yellow and black hairs and yellow scales. Palpi white excepting the apical half which is made up of mingled black and greenish yellow hairs and scales, with some intermingled white scales. Antemnae testaceous, marked along the inner and especially on the under side, as well as at the apices of the joints interiorly, with silvery white; the club lnteo-testaceous on the naked portion, blackish brown on the scaled, excepting where it is overlaid with white, as on nearly the whole of the under smrface. Thorax covered with sellow and blackish brown hairs above, beneath with pale yellowish white hairs and yellowish scales; legs luteous, overlaid heavily on the femora and tibiae, very sparsely on the tarsi, with white scales; spines and claws luteous.

Wings above pale canary yellow with dark brown markings. On the fore wings the brown markings consist of a large apical spot which is bounded by a rery oblique line which runs from a little beyond the middle of the costal border to the middle or scarcely below the middle of the onter border, there merging into the upper of the trimgular spots which mark the tip of the lower median nervules; it is marked by a slight jog as it crosses the main subcostal nervure; in addition there is a small black spot in the middle of the outer half of the upper median interspace, and on the inner margin of the wing is a broad brown or blackish brown helt leaving only a yellow line hetween it and the margin, extending from the base almost to the outer extremity of the wing, and enlarged apically by merging in a large hrown spot, occupying the middle half of the lower median interspace. Hind wings not unfrequently tinged with orange in the female and there more heavily marked than in the male; but in both there is a brown belt following the whole extent of the costo-subcostal interspace excepting its extreme apical portion where it abruptly terminates; and excepting, in the male, a basal yellow or orange clongated spot; the extremities of all the nervures in the npper half of the wing are also marked in brown, in the female occasionally connected along the margin with a faint indication of a transwerse stripe in the middle of the outer balf
of the wing, always more distinct in the upper than in the lower half of the wing and usually confined to the former; fringe of all the wings pale yellow, more or less mingled with brown mext the brown parts of the wing.

Beneath : fore vings very pale greenish yellow with a slight and narrow ( $\delta$ ), or diffused and more distinct orange ( $f$ ) glow in the costal area; apex of the wing much fleckel with brownish scales, especially in the female, where they sometimes form a spot almost as distinct as above; the markings of the inner margin of the upper surface are repeated beneath but often much obscured or made gray by a mingling of yellowish and brownish scales; but there is always in the outer half of the wing a distinct series of three roundish spots in the median and medio-submedian interspaces, that in the lowest median the largest. Hind wings with the same ground color as the fore wings ( $\delta$ ), or very much obscured by greenish brown so as to make the whole wing of a greenish gray color with a minute whitish spot at the divarication of the subcostal nervure and a pallid clond in the outer third of the wing ( 8 ). Expanse of wings, $22-30 \mathrm{~mm}$.

This dainty little butterfly has a pretty wide distribution, chicfly in the southwestern United States and Mexico. Curiously it does not appear to occur in the United States anywhere east of Louisiana, although it is found in Cuba and Jamaica. It extends also throughout Mexico and into Central America, and in the United States from the Mississippi to the Pacific. How far north it occurs on the west coast I do not know, hut both Mead and Reakirt report it from the Rocky Mountains of Colorado, at from 7500' $8000^{\prime}$, and east of that it is found in Missouri and even in Illinois. I have seen it abundant about St. Louis.

It flics at the end of June and in July and doubtlese at other times, but excepting that Cockerell took a specimen in southern Colorado on November 1 , nothing further is anywhere reported regarding its seasons or history, and its early stages are quite unknown, though $\mathrm{Mr}_{\mathrm{r}}$. Elwards has followed them, and will doubtless soon publish the details.

## TRIBE ANTHOCHARIDI.

## SYNCIILOE HÜBNER.

Imago. Head of moderate size, densely clothed with erect hairs. Front exceptionally protnberant and tumid, much broader than high, the middle projecting farther beyond the eyes than they in front of the antennal pits; above with a tolerably sharp and distinct longitndinal sulcation; behind the antemnae a broad and very deep, transverse sulcation. Eyes not atall full, naked. Antennae much shorter than the abdomen, inserted tightly in deep pits, open outwardly, bringing the second joint to the level of the summit; separated by twice the diameter of the second joint; composed of about thirty-one joints, of which nine form an oval, flattened club, three times as long as broad, more than four times as broad as the stalk, increasing regularly in size on the basal half, broadly rounded and scarcely angulate at the tip, the broadest joints about four times as broad as long, the middle joints of the stalk about three times as
long as broad. Palpi very long and slender, projecting forward beyond the eyc by the diameter of the latter, the terminal joint nearly equalling the basal in length, but not over a third as long as the middle joint.

Fore wings triangular, elongatel, the apex produced; costal margin nearly straisht, except at the extreme, roundly angulated tip, nearly a fourth longer than the inner margin ; outer margin gently and prettr regularly convex. Third superior subcostal nervure doubly forked; cell scarcely more than half as long as the wing. Ifind wings subquadrate in form, the costal marsin clistinctly, though broadly, angled before the tip of the rather short costal nervure, the part beyond subparallel to the imer margin.

Hind femora of male hardly more than two-thitels as long as the fore femora. Foretibiae half as long as fore femora; first joint of fore tarsi as long as tibia, or as the other subequal tarsal joints together. Hind tibiae nearly twice as long as hind femora, and scarcely shorter than first four tarsal joints; first tarsal joint scarcely longer than the next two together, the others subequal. All the spines very short and thin. Claws elongate, not very divaricate, equal and mearly straight on the basal half, beyoud strongly curved. tapering, pointed and bifid. Paronychia forming a simple, tapering, bluntly pointed, pilose lube, a little shorter than the claws.

Mature caterpillar. Body with the segments divided into sis sections, of which the first is as large as the two succeeding. Besides the minute papillae bearing long, slender hairs everywhere seattered over the surface, there are a very considerable number of much larger, high, conical papillae, bearing stiff bristles, terminating in slender hairs, which are arranged rather more conspicuousty in transverse series on the sections of the segments than in longitudinal rows, and they are found almost exclusively on the linst, second and fourth sections; they are two or three times as numerous as in Anthocharis, ancl much less regular.

Chrysalis. Of the type of the tribe, but the front and hind halves of the body less bent than usual, though subegual, the dorsal surface being nearly straight from one extremity to the other, the ventral bent at a very broad angle. Frontal promibence slender, conical, pointed, as long as the wings.

Synchloe appears to be tolerably abundant in species, occurring in the north temperate regions of both hemispheres; in the Old World from ocean to ocean, in the New, as often happens in such cases, only in the western half of the continent. The characteristics of the group are very similar to those of other Anthocharidi, they being early spring butterflies, appearing but once a year upon the wing, but they seem never to have the tip of the fore wings adorned with an orange patch.

## SYNCHLOE OLYMPIA.

Anthocharis olympia Edw., Trans. Am. ent. soc., iii : 266-267 (1871); Butt. N. A., ii: A11thocaris 1, figs. 1-4 (1874); Streck., Lep. rhop, liet, $64-6 \overline{5}$, pl. 8 , tigs. 9,9 (1874);

French, Butt. east. U. S., $117-118$ (1886).
Zegris olympia Kirb., Syu. cat. diuru. Lep., S06 (1877).

[^10]the eostal margin, heavily flecked with black brown -cales, which are more profuse next the interior limit of the patch at the costal and onter mareins, and least heary in a romndish patch. larger and clearer in the female than in the male, situated on the costal margin just without the darker interior edge; in addition the nervules in this portion of the wing are generally more hearily flecked with brown, and there is sometimes a slender white line clown the middle of the interspaces; the costal margin as far as the tip of the cell irrorate with blackish brown, and the extreme base of the wing, enpecially beneath, heavily fleckerl with inky black scales. Hind winys with almost no markinge except such as are due to their fliaphanous nature; there are, however, three small black spots at the tips of the costal and two upper subcostal nervules, the first mentionel the largest, sometimes ohsolete, and perhaps more distinct in the female than in the male.

Beneath: of the same white as above. Fore vings with the onter limit of the cell marked with a few blackish brown scales forming a dusky bar; midway between it and the apex of the cell a narrow, blackish brown bar descends to the main subcostal nervure, pretty heavily flecked, especially below, with grecnish yellow scales; the costal margin above the cell is irrorate with black as above, but more distinctly, and there is found a faint wash of greenisb yellow scales at the extremity of the last median nervnle, following the nervule back for the width of an interspace. Hind wings exquisitely marked with greenish yellow, mingled with blackish fnliginons scales in very irregular, rather narrow, vermicnlate stripes, in which the dark scales are usnally not found at the extreme margins, which thus appear to be washed at their edges with yellow, the effect of the whole being a light greenish gray; these markings may be said to consist mainly of four separate parts : a narrow, transverse basal stripe, more regular than the rest, nearly egual throughout, running from the costal margin midway between the base and tip of the costal nervure in a straight course to the cell, transverse to the nervure, and then curving around toward the base of the wing ; a second much more irregular stripe crossing the middle of the wing, starting from the costal margin at the tip of the costal nervure, and running in a nearly direct course, curved inward a little at the extremity, to the middle of the inner margin. crossing the extremity of the cell; it generally encloses a small, partly open white spot on the interior side in the first subcostal and on the outer side in the second subcostal interspace, and another one on the outer side at the extremity of the cell; it also sends a slont at right angles to its course toward, but only half way to, the base of the inner margin at the median nervure; this shoot is as broad as the belt itself, and terminates abruptly with a little horn thrust toward the inner margin; the third is a large, semi-lnnate, strongly arcuate spot, resting by its two horns and a large depending middle tooth upon the outer border at the two lowest subcostal and the last median nervules, and connected with the preceding by a gently sinuous stripe which follows the outer limit of the median nervure; near the tip of the costal margin, midway between this outer patch and the mesial belt, is the last portion of the marking, a rather narrow, slender bar clepending from the margin, running as far as the middle subcostal nervule, where it nearly meets a slender horn projecting from the middle stripe; the entire under surface of the hind wings, and especially of the basal half, is very sparsely clothed with tolerably long, erect, white bairs. Expanse of wiugs, $\delta, 40 \mathrm{~mm}$; ㅇ, 43 mm .

This butterfly is found in the states tributary to the Mississippi-Texas, Missouri, Kansas and Nebraska on the west, Indiana and Illinois (Bureau Co.) on the east, as well as West Virginia on the Kanawha River. It has only been taken at distant intervals, but doubtless extends over a wide extent of country between the Alleghanies and the Great Plains, south of about $40^{\circ} \mathrm{N}$. Lat.

Like the allied species of Anthocharis, it flies early in the spring, appearing in West Virginia in April, but of its early stages or further history we
know nothing. Comparing it with another species of the genus, ansonides, Edwards says it is more delieate and less strong of wing, " and of a low, uncertain and tremulous flight. In West Virginia it accompanies genntia, and might easily be mistaken for the female of that speeies, frequenting, with it, eultivated grounds, gardens and meadows."

# SUBFAMILY PAPILIONINAE.

Euphoeades chalcas Hinhn., Verz. bek.

schmett., s3 (1816).<br>Princeps heroicus chalcus Hübu., Samml. exot schmett., i (15)f-21).<br>Papilio calchas Boisd.-LeC., Lép. Amér. sept., $17-19$, pl. כั (1s-2?-80);-Boisd., spec. <br>Puilin fuco-maculatus Goeze, Ent. beytr., iii: 87 (1月7).

Imago. Head and body blackish brown, marked with a moderately broad, pale yellow stripe which ruus from the tip of the patagia forware in a straight line to the imer edge of the eye, which it encircles, includes the palpi, and raus down the breast to the base of the fore legs; a similar yellow stripe follows down the middle and hiud coxae, and the abdomen is marked with a broad, micl-lateral, yellow band which terminates on the clasps and occupies the middle of then; besides which there is a similar lateroventral band on the terminal two-thirds of the abdomen, fading out anteriorly to a thin line which runs angularly upward to the base of the hind coxae; antennae reddish chocolate, paler above than below, but the club infuscated, especially above.

Wings above blackish brown with a chocolate tinge, with a premarginal series of roundish, paie yellow spots and an extra-mesial series of large yellow spots, independent and generally triangular on the fore wings, more or less quadrangular and conthent on the hind wings. On the fore winys the spots of the submarginal serics are tolerably uniform in size, round, and abont one-half an interspace in diameter, their outer limits at an interspace's distance from the outer margin; thongh sometimes almost perfectly straight, the series is always simuous to a slight degree, the spots in the two lower median interspaces being removed a little ontward; the extra-mesial row of spots in the same interspaces is more irregular, those in the subcostal interspaces being as far removed from the submarginal spots as they from the margin, and are short, triaugnar or the uppermost quadrangular, elongate; the spots in the next four interspaces seem to run in a line slightly oblique to the general course of the series, the uppermost oue being removed inward slightly, and the outermost outward; these are always larger, triangular, the apices imward, with the exception of that in the subcosto-median interspace, which, at least in the males, is frequently as broal or nearly as broad interiorly as exteriorly; the spot in the medio-snbmedian interspace is sublunate, sometimes much broader than long, while that in the interspace below is subtriaggular and clongate, its apex outward; there is besides, particularly in the males, rarely or but faintly in the females, a transverse bar in the cell, traversing the middle of its apical third, reaching neither limit, but more in the upper than inthe
lower part of the cell; in the slender, subcostal interspaces between this spot and the outer upper spot of the extra-mesial series there are slender streaks of yellow followed in the penultimate, superior, subcostal interspace by a large, triangular, yellow spot, midway between the base of the interspace and the spot beyond; the general tone of the ground in the outer half of the wing is slightly darker than in the basal half; there are a few greenish yellow scales flecking the costo-subcostal interspace faintly above the apical half or more of the cell. Hind wings: the ground of the outer half of the wing is black, in more marked contrast with that of the base than on the fore wings; the submarginal series of spots consists of transverse, lunulate bars crossing almost the entire interspace, subparallel to the outer margin of the same interspace with the exception of that in the costo-subcostal interspace which is rather subparallel to the other spots; the spots of the extra-mesial band are completely confluent into a band, barely, if at all, interrupted by the nervures; it is moderately slender with regular, arcuate, interior margin, somewhat powdery, especially in the middle of its course, usually broader in the male than in the female, and somewhat irregular in its direction, its interior border in some cases crossing the wing at the apex of the cell, at other times beyond it by the entire width of an interspace (which is ordinarily the course in the female), and at others, at least in some males, including the tip of the cell in the band, in which case the outer limits of the cell are marked in black; the exterior margin of this belt is clearly marked in the upper part of the wing, passing in a series of strong arcuations as far as the middle of the wing; below which the limit of the band is more regnlar but obscured by a heavy powdery of greenish yellow scales which cover the greater portion of the median interspaces beyond the baud, including by their abseuce obscure, black spots in the middle of the interspaces, directly following the band and which are seated upon vague, powdery spots of blue scales, extending as a faint band of lunules across the entire wing, generally snbobsolete and found only in the female; the anal angle is occupied by a large, black spot which is in continuation of the black spots of the preceding interspaces, including within it a large, blue, powdery lunule, followed behind in both sexes, and in front always in the female, sometimes in the male, by orange, which on the inner side infringes upon the yellow extra-mesial band; at the extremity of all the interspaces the dark fringe is interrupted by yellow which extends as a distinct lunule upon the ground of the wing itself.

Beneath, with the ground color a little paler than above; the fore wings with the same markings as above, slightly enlarged and with the transverse bar at the end of the cell distinct in both sexes; in addition there is a vague, powdery, straight, oblique stripe crossing the base of the wing and especially of the cell, which is in continuation, when the wings are spread, of a more distinct stripe which will be described upon the hind wings; this is always more distinct in the male than in the female, and is occasionally wholly absent from the latter. Hind vings with the basal half uniform, excepting for a deepening at the extreme base of the wing and for a yellow edging to the basal lobe previous to the tip of the precostal and a straight, or slightly arcuate, narrow yellow streak, broader above than below, which runs from the costal margin where it is sometimes paler, nearly to the middle of the first median nervule, following down this latter along its inner edge; the outer half of the wing is much variegated, the marginal lunules in the interspace are more distinct than above and are almost white; the submarginal series of lunules are also more highly developed but are pale orange with white ends, and that which occurs in the medio-submedian interspace is united with the marginal marking, showing its compound nature by the deep indentation of its inner side; the mesial band has become a series of closely adjoining, but distinct white lunules, heavily marked with orange, so as in many cases, especially in the female, to be more orange than white, but always white along the inner margin and here invariably removed farther toward the apex of the wing, never including the cell, although occasionally touching it in the male; they are margined externally with round, deep, black spots, including in each interspace a powdery spot which leaves only a lunulate black edging to the extra-mesial band; the powlery spot is more dense toward the
base of the wing, and is here caerulean blne, while beyond this the scales are more sparse, are greenish yellow and sometimes fill the larger part of the interspace nearly to the submargimal markings. Expanse of wings $\delta, 100-109 \mathrm{~mm}$; $;$, $112-116 \mathrm{~mm}$.

The following descriptions of the early stages are those given by Edwards with only sucli changes iu phraseology as seem necessary.

Egg. Spherical, a little flattened at base; color greenish yellow.
Caterpillar. First stage. Head obovoid, a little depressed at top, smooth, shining, color rellow-brown, a shade clarker than body. Body at the end of this stage cylindrical. greaty thickened from the second thoracic to second abdominal segments; beyond tapering to the eighth abdominal segment, then thickening to end, the back aud sides after second abulominal a little incurved; the first abdominal segment has a thin square ridge and on each curve of same a thick fleshy process, louger than others on body, thickly beset with straight hairs; there are two rows of similar processes, supralateral, smallest on the narrow segments, colored as the segments they stand on, those on the eightl and nintl abdominal segment considerably larger than any others except on the first thoracic segment; besides the supralateral rows, are two subdorsal running the whole length of body, and one row on side, another along base; all these are small, simple tuberculations with hair on end; color of body brown-yellow marked with white; a white band, not very clearly defined, especially on its lower edge, passes along the side of the seconcl thoracic to the fourth abdominal, turning up on the fourth abdominal to elge of dorsum, the two extremities there not quite meeting ; the eighth and uintb abdominal segments are white; under side greenish brown; all the legs same. Length. 2.5 mm ; near the end of the stage, 7 mm .

Second stage. Head subcordate, finely granulated, shining yellow-brown, with fine hairs. Boty with same general shape, at irst the clorsum on the thickened segments is sinooth and rounded, but after a few hours becomes flattened a little, and corrugated; the first thoracic segment has a thin, high, square topped ridge, the corners produced, and each bears a short thick process, pilose; on the eighth abdominal segment are two short subconical processes, on the next two like them but larger, and these four form part of the two supralateral rows, which are almost suppressed on the second to sixth abdominal segments but are distinct on the seventh, the two subdorsal rows of tubercles are minute; color of bocly yellow brown, darkest on posterior lialf, the anterior segments a little red-tinted; the white lateral band as before, but distinct, white; the dorsum and mpper part of the side of the eighth and ninth abclominal segments and a little of the seventl pare white, the lower part of the side less pure, the shield sordicl white; over the white band, on the third thoracic segment is a large, sub-oval, black ocellus in a aarrow yellow ring; this ocellus is mostly occupied by a prominent, rounded, black process with many short black hairs on it. Length, 8.4 mm .

Third stage. Head as before, and it and the first thoracic segmeut are one color, honey yellow. Body of same shape, and as before, the dorsal area on thickened segments becomes corrugated and flattened and depressed some hours after the moult, and the depression is enclosed by an elevated oval rim; the second thoracic segment is a little excavated on clorsum on anterior part ; the first thoracic seginent is a square topped ridge, but the processes have passed away; on the eighth and ninth abdominal segments the processes as at previous stage, but the rest of the laterodorsal rows have disappeared, and in place of part of them are slight, rounded elevations, like those of the subdorsal rows ; so that on the second thoracic segment there are two subdorsal and two laterodorsal rows of these knobs, but two subdorsal only on the last thoracic and first two abdominal segments, on the flfth and sixth abdominal segments are two subdorsal, little, round, lilaceous spots; color yellow brown to dark brown, the anterior parts having most yellow; the sides of the posterior segments of a black hue; the white side stripes as before; eighth and ninth abdominal segments white, the shield greenish brown above, but white below, and the anal claspers white; the white extends into the sides of the seventh segment, but the brown dorsal area runs back in a sharp point nearly to the eighth; on the last thoracic segment the eye-spot is large, flattened in front and there velvet-black, but behind this is a prominent, black, vitreous, bead-like elevation, smooth
and without hairs; instead of a complete and uniform ring there is a thickening of the gellow above and below the eye-spot, and the ends are narrowed, se that the appearance is much like that of eye-lids. Length, 9 mm . One larva differed from all the rest, being uniform light, yellow brown, the white area on the seventh and eighth abdominal segments yellowish.

Fourth stage. Head as before, but greenish yellow. Body with same shape and gencrat color, the anterior segments a little darker, and their surfaces finely and thickly, but indistinctly, dotted green; the middle segments lighter colored and distinctiy dotted green; the side bands salmon color, the last segments a reduer salmon; ninth abdominal segment white above base at extremity; along base of body, with and a little above the spiracles, a white, macular band; on dorsum of ninth abdominal segment two small, conical, white processes (none on the preceding) ; on dorsum of first abdominal segment are two abbreviated bars of red lilac, one on each side, in the laterodorsal row, and on the second to sixth abdominal segments is a small, rounded, lilac spot on each in same row; on the side of the fourth to sixth, one similar spot to each; on second thoracic to secoud abdominal segments low, rounded knobs as at previous stage; below the basal ridge is a small, indistinct, blue-lilac spot on each segment from the second to seventh abdominal segments; the ocellus as at previous stage, the buff ring now open at anterior side. Length, 20 mm .

Towards the last of this stage the brown area has a green tinge, and the green dots become quite distinct and the side bands are greenish; the circlet of the eye-spot changes to red-buft. Later the top of the anterior segments became olive green, the dorsum after the first abdominal segment light green, edged down the sides by dark green; the side band pale green, as are the last segments; uuder side pale, greenish brown; the lilac spots unchanged; the spots below spiracles blue.

Last stage. Head subovoid, bilobed, granulated, with a dull gloss; color olive green. Body cylindrical, the second thoracic to first abdominal segments much thickened, arched dorsally, then tapering to last; color dull, velvety green, on second and third thoracic and first, eighth and ninth abdominal segments ncarly solid, but a little specked with lighter green; the other segments light and dark green in fine markings; the basal ridge whitish green; under this is a fine black line from the second thoracic to eighth abdominal segments, and on the second to serenth abdominal is a subtriangular blue spot in black, edging on each segment just below the line; the first thoracic segment has a narrow, yellow ridge in front, nearly flat on top, the curves rouniled; on anterior side of this and next it is a black, subdorsal clash on either side; behind the ridge is a black, rough, or shagreened uarrow band; the scent-organs light, jellow-brown; ou the side of the last thoracic segment is a black ocellus, upon which rises a rounded, vitreons. black process, the circlet orange red, having a black stripe within its anterior edge, and a blue spot on its upper outer side; on the first to seventh abdominal segments are four rows of small, blue-lilac spots, each in tine black ring, two of the rows being laterodorsal, two lateral; on the eighth abdominal segment only the two laterodorsal rows are present, on the ninth neither ; on the dorsum of the first abdominal segment at posterior edge is a buff spot just outside the lilac spot and touching it. Under side deep ochre buff; feet and legs greenish brown. Length, 40 mm .

Gradually the larva changes, the specks disappear on the anterior and also on the last segment, so that the extremities are solid green; on the middle segments the specks and marks become less distinct; the ridge at base becomes yellow, the whole under side port wine color; all the lilac spots change to bluish, the two spots on the first abdominal segment to brown-buff.

Finally, before suspension, the whole surface becomes dull, ochrey yellow, the red of lower side becomes dull and yellowish, or dull salmon, the lilac spots on back change to pale black, but the spots below the basal ridge retain their blue color, but are dull.

Chrysalis. The ventral side highly arched, the dorsum much incurved, the former narrow at summit, particularly on the thoracic segments, rounded, the sides sloping; the dorsum rouncled, the sides somewhat flattened to the lateral ridge, which is promiment, carinated, and extends from end to eud; head-case long, flattened transversely
and abont equally on the two sides, narrowest at base and widening gradually to the tips of the ocellar prominences; these 'are long, subpyramidal, divergent, the space between excavated roundly; mesonotnm low, the sides very little convex, on the top a very small, pyramidal elevation; surface all finely granulated; color variable; one phase shows the whole dorsal side a delicate green, with a darker green medio-dorsal stripe from mesonotum to last segment; below mesonotum two subdorsal low red tubercles, one on either side; on either side of the abdominal segments two rows of dull lilac points, forming a cross row of four to 'each segment; whole ventral side one shade of green, a little darker than dorsnm and less yellow; the lateral ridge cream color more or less marked by a red line, which 'broadens on the process of head; on the ventral side below the head two red dots near the middle line; a series of white dots along the margins of wing cases; below the ridge, on last segments, are traces of blue spots. Length, 35.5 mm . ; breadth, 9.6 mm .

Another resembles the above described, except that there is a yellow shade over the dorsal elevation and the medio-dorsal stripe is red. Others are quite unlike these; the bead case and mesonotum are yellow brown, and the rest of the dorsal side is yellowbrown with a pink tint; the stripe and the ridge brown; the dorsal spots blne, and dull blue spots below the ridge; whole under side light yellow-brawn.

This fine butterfly seems to be confined to the southern half of the United States, east of the Mississippi, not extending into Texas nor reaching northward beyond Virginia so far as known. Cadet, Missouri, is the westernmost point from which I have heard of it. It appears to be peeuliarly a butterfly of the southern Atlantic coast, where it is very common.

There would seem to be some doubt about the food plant of the caterpillar. Edwards quotes Dr. Wittfeld as obtaining the eggs and feeding the larvae on red bay, Persea carolinensis, a plant which Edwards could not obtain, but he reared them readily on Sassafras, a very closely allied genus of plants. Dr. Wittfeld, however, writes me that the food plant is Magnolia glauca, which he calls "red bay" (more properly "sweet bay") and Abbot long ago figured the larva upon Magnolia glauea. Possilly both of these plants are fed upon by it, but plainly Lauraceae form a part of its dietary.

In Florida there must be at least three broods annually, and the winter is passed by part in the chrysalis, by part in the imago state; for Dr. Wittfeld had the butterflies escape from wintering ehrysalids early in February; obtained eggs, which must have come from at least a second brood, on June 6; these gave the butterflies at the end of July ; other eggs obtained in the middle of August gave caterpillars which went into chrysalis for the winter in September ; some September chrysalids gave the imago the same year, some early in the next. The egg period is five days in June; the caterpillars require about a month to mature and the chrysalis state lasts fifteen or sixteen days in July. Edwards found the egg-period four or five days in West Virginia and the successive larval stages four, two, three, four and nine days.

The eggs are usually laid on the upper side of tender leaves. The eaterpillar lives exposed on the upper side of leaves, aceording to Dr. Wittfeld. Edwards says "they are sluggish, like the larvae of troilus, and in
general behave in same way, at all stages resting on a lining of silk, which they had spun on middle of the leaf, whereby the leaf is curled or drawn together so as to afford a concealment." But in New England, the caterpillar of troilus is completely concealed, the edges of the portion of the leaf used for shelter being tightly elosed. "This," he continues, "they rarely leave, and then only when hungry, feeding on the end of the leaf until it becomes too small for a hiding place, after which they betake themselves to another leaf. But these larvae do not cut into the side of the leaf and fold down the eut portion as troilus [sometimes] does. This Dr. Wittfeld states in reply to my enquiries."

Dr. Wittfeld further says of the habits of the imago, as quoted by Edwards :-"Palamedes roosts on the highest tree it can find, oak or palmetto. I have seen four to six near sundown fluttering about the tree, where they finally settled and remained. Sometimes three or four so roost on one large palmetto leaf." And he adds in notes sent me "with spread wings," which appears very remarkable.

The insect is attacked by Pteromalus vanessae (89:3) which Dr. Riley reared in April from chrysalids sent by Mr. Barlow of Missouri.

## PAPILIO LINNÉ.

## PAPILIO BREVICAUDA.

pl. 8, fig. 18 (1874).
Papilio asterius var. a.brevicauda Streck., Cat. Alwer. Macrolep., 71 (1878).
Papilio asterius var. b. anticostiensis Streck., Cat. Amer. Macrolep., i2 (18is).
Papilio polyrenes var. brevicaula Coup., Can. ent., iv:202 (15:2).

Imago. Head and appendages as in polyxenes. Wings with the same colors as in that species. Fore vings rich black brown with precisely similar markings in the male and female, viz., a submarginal series of round yellow spots tending to become sublunulate on the lower half of the wing, donble in the medio-submedian interspace, found in all the interspaces, at the centre at an interspace's distance from the border; an extra-mesial series of roundish triangular, large, sublunnlate spots, their common exterior limit nearly straight, subparallel to the outer margin and removed from it by abont two and a half interspaces in the middle of the wing; the inner extremity of all of them is powdery, the outer limit clearly defined; those in the medio-submedian and submedio-marginal interspaces are nearly quadrangular; above this they decrease regularly in size to the spot in the subcosto-median interspace, above which they increase again in the same degree, the spot occnpying the extreme base of the ontermost subcostal interspace interrupted by a large, long oval, blackish brown spot which occupies all or nearly all its entire width in the basal thrce-fifths of the spot, usually breaking it into two entirely distiuct portions; in addition there is a large ronnd spot, generally larger than any of the snbmarginal spots, surmonnting the last divarication of the subcostal nervure, and a transwerse bar of yellow mark the extremity of the cell. On the hind voings the markings are again precisely identical in the two sexes; the same two
series of spots that are found upon the fore wings are here repeated; the extra-mesial series as a narrow and nearly equal belt interrupted ouly by black nervures, bent beyond the cell, running from the costal margin, its interior limit at the middle of the margin, in a direction straight toward the anal angle, a direction which is bent beyond the cell so as to run to the inner margin, its outer limit removed from the anal angle by the wilth of an interspace; this belt is externally slarply definet, but interiorly is powdery; the outer limit is again lunulate and the spots in general are longer than broad, espeeially in the middle of the wing, and from the character of the interspace more or less cuneiform; the outer point of the cell is marked by a slight powdery patch of yellow scales; the onter series of yellow spots consists of widely separated, distinctly lunulate, clearly defined spots, their auter limits remored from the margin by the width of half an interspace; they are yellow, but occasionally show a slight tendency, especially in that in the costo-subcostal interspace, to be sufiused with orange; that in the lowest median interspace becomes altered to a transverse, long oval stripe; at the anal angle is a large ocellus, composed of a large, ceutral, black spot, seated on the margin surrounded by a broad amnulns, yellow below and orauge above: between these two rows of spots the interspaces are more or less heavily flecked with bright blue scales which, above the ocellus at the anal angle, form a distinct semi-annulate lunule; the fringe black brown interrupted in the interspaces opposite the spots with yellow.

Beneath: with the same colors as in polyxenes, and the markings of the upper surface mainly repeated, the males and females again not differing; all the yellow spots, however, especially upon the hind wings, but with the exception generally of the other spots of the fore wings, more or less heavily bathed in orange, especially mesially, the orange being frequently surrounded to a greater or less extent with yellow, which is here less brilliant than above. Between the two rows of spots of the hind wings the black ground is sprinkled sparsely and with tolerable uniformity with pale greenish yellow scales which are supplanted by lunules or sagittate spots of bright blue scales, more densely clnstered a little beyond the outer margins of the extra-mesial spots and enclosing between them and the spots the black ground in the shape of slender equal bars of a deeper black than most of the ground; ocellus moch as above. Expanse of wings, $\delta, 74 \mathrm{~mm}$; $\%, 80-88 \mathrm{~mm}$.

This interesting butterfly differs from P. polyxenes, to which it is most closely allied, in that both sexes are alike, corresponding to the colors and patteru of the male of polysenes; but in addition the spots of the mesial band on the fore wiugs are more or less orange, and on the hind wings below are orange, broadly capped and margined with yellow; while the tails of the hind wings are only about one-third as long as in polysenes, and the outer margin of the fore wings is distinctly couvex.

The following descriptions of the early stages are those of Mr. Edwards, slightly modified in form :

Egg. Splierical, flattened at base; pale yellow.
Caterpillar. First stage. IIead black, pilose. Body cylindrical, the anterior segments thickest, and a little arched; color pale black; a white patch on dorsum, on fourth and part of third abdominal segment; the spines are in six rows, one subdorsal and two on either side; these are black and rise from pale yellow tubercles; each sending out a few black hairs. Leagth, 2.5 mm ,

Second stage. ILead black, shining; with a white spot in front and one on either side. Body black-brown, the patch white and extending well down either side; the spines as before, their bases pale yellow. Length, 6.4 mm .

Third stage. Head as at previous stage. Body black, the patch as before; white marks over the feet; the bases of the spines chrome-yellow. Length, 10 mm .

Fourth stage. Head as before. Body black, with narrow, white stripes at the junctions of the segments; white also on the sides of third and fourth abdominal segments, but not on dorsum; white poiuts on the last segment and over feet; the yellow at bases of spines is brighter. Length, 20.3 mm .

Last stage. Head obovate, either yellow greeu or pale green, marked in front by two
oblique, black stripes, which nearly meet at top; two others on the sides, and between the front and side stripes at base is a short, narrow stripe; on lower front face a rounded, black spot: the retractile horns bright yellow. Boly cylindrical, slender, thickest at last two thoracic segments, tapering slighty from last thoracic to last abflominal segments, and rapilly toward the heal: the surface smooth, the tubercles of previons stages being suppressed, except those of the two dorsal rows which are reduced and scarcely elevated, and under the glass are seen to have a pencil of very short hairs each; when at rest the anterior segments are contracted and arched; the midde of each, from the first thoracic to the eightlo abdominal, crossed by a black stripe or marrow hand, broken on the middle of side after the first abdominal segment ; from the last thoracic semment, divided a second time near its extremity, a triangular section being cut off on the posterior side; on the nintb abdominal segment the band is divided into three spots, the central or clorsal one being rounded; behind these are two subdorsal, round spots, and on either side a long, oblique mark; the anal shield black; there is also a black stripe between each pair of segments, broadest on dorsum and diminishing to the middle of the side where it disappears; these are scarcely visible, except when the larva is in motion; there is also a line of small, black spots along base of body, one on each segment from the first thoracic to the second abdominal, and on the seventh to ninth abdominal, two on the third to sixth abdominal, and there is a spot over each leg and proleg; on each side are three rows of chrome-yellow spots, those of the two subdorsal rows being round and placed just within the tubercles, and on the front edges of the bands; so the spots of the nther rows on the second and third thoracic and first abdominal segments are on the fronts of the bands; but after this they divide them, the middle row being round, the lower row straight and oblique, filling the space between the band and triangle; legs tipped black; color of body bright pea-green, changing to yellow green on the sides; or a creamy white, tinted dorsally with delicate green, fadiug into white on the sides. Length, 38 mm .

Another larva at maturity was black, with white lines between the segments, ant pale green between some of them, especially the anterior ones and the last two; much white along base of body.

Chrysalis. Cylindrical, thickest in middle; the surface rough, corrngated; head case produced, ending in two subtriangular processes, the space between them concave; mesonotum prominent, pointed forward, subpyramilal; color green, on dorsum yellowish, on ventral sitle pale; the wing cases dark; on abdomen two subdorsal rows of small, rounded tubercles. Length, 25.4 mm . ; greatest breacth, 7.6 mm .

This butterfly has a narrow and peculiar range, which shows it to have been an offshoot from the ancestors of P. polyxenes at no very distant epoch. It is known only from Newfoundland and the shores and islauds of the Gulf of St. Lawrence, both north and south, as at Godbout and Percé.

It is single brooded and winters in the chrysalis. The butterfly flies in June and the first half of July, and is most abundant in the latter half of June; egge have been obtained from June 14 for a month, but their period has not been stated; the caterpillars grow rapidly for so high a latitude, and begin to go into chrysalis toward the end of the first week in August; carried south some chrysalids gave out the butterfly the same year, one in eighteen days.

The eggs, according to Couper, are laid singly on the upper surface of a leaf, near the edge. The caterpillars feed on Archangelica gmelini, Heracleum lanatum, parsley, Apium petroselinum, and doubtless other Umbelliferae; when young they feed on the upper cuticle, and on cold
nights hide in the leaves; they are very susceptible to cold, prolonged darkness or confinement of any kind; when not feeding "they either rest upon the leaves in full sunlight, or bask upon the stones and coarse gravel among which their food plants grow. These stones are often heated by the sun during the day to a temperature of $90^{\circ}$ to $100^{\circ} \mathrm{F}$., and retain a part of the warmth over night." (Mead.)

# HESPERIDAE. 

TRIBE HESPERIDI.

RHABDOIDES* gen. nov.

Imago. Head large, compact, sessile, the front mesially and strongly tumid, much surpassing the front of the eyes, the lower edge marginate; vertex depressed, nearly flat. Eyes very large, very full, circular, naked. Palpi short and rather small, the basal joint tumid, larger apically than at base, produced apically on the outer side, no longer than broad; middle joint sub-cylindrical, rounded at each end, less than four times as long as hroad; apical joint minute, orate or subconic, not so long as the width of the middle joint. Antennae separated at base hy three times the width of the hasal joint, exclusive of the crook a fourth longer than the ahdomen, composed of about forty-eight joints of which about twenty-eight form the very gradually incrassated, cylindrical or elongate, fusiform club, which is nearly as long as the stalk and bent rather beyond the middle, the crook tapering gradually to a delicate pointed tip; in the middle of the stalk the joints are abont three times as long as broad; on the broadest part of the club about twice as broad as long.

Fore wings shaped as in Achalarus, with which also the neuration essentially agrees. Internal nervure delicate but distinct, short, distant from the submedian nervure and ranning into it. Hind wings rounded triangular, considerably longer than broad, especially in the male where the submedian area is produced, so that the outer margin is more rounded in the female than in the male; in both it is gently crenulate between the nervures; neuration as in Achalarus but with the subcostal and second median fork almost equally distant from the base.
Fore femora slightly longer than hind femora, nearly twice as long as fore tibiae, and almost as long as fore tarsi; first fore tarsal joint fully as long as the rest of the tarsus. Hind femur three-fourths the length of the hind tibia and half as long as tarsi; first joint of tarsus equalling the remaining joints together, the fiftly equal to the fourth, all clothed bencath with three rows of slender spines, the apical ones of each joint larger than the others. Claws very small and delicate, bent in the middle and finely pointed. Paronychia well developed, the upper lobe claw-like and as long as the claw, tapering hut little, the other as long, forming a broad iuferior flap.

The illustrations of the early stages by Abbot do not permit one to mention any generic features, excepting that the chrysalis is exceptionally slender and tapering for one of this group of 1 Iesperidi.

This is a small group composed of a few species only, found exclusively in America and especially in the tropics; how far it ranges I am unable to say, but in the United States the only species known is that here described, whose early stages were figured long ago by Boisduval and LeConte from Abbot's drawings, and which give us all that is known of them.

[^11]
## RHABDOIDES CELLUS

Eudamus cellus Boisd.-LeC., Lép. Amêr. sept., pl. 73 (1833) ;-Freuch, Butt, east. U. S., 371-372 (1886).

Spathilepia cellus Butl., Ent. month1. mag., vii: $ิ 7$ (1870).

Cecrops festus Gey, Hübn., Zütr exot. sehmett., v:27, figs. 907, 90 s (1837).

Figured also by Glover, III. N. A. Lep., 11. B. fig. 25j; pl. F, fig. 13, ined.

Imago. Head covered above with mingled dull tawny and black-brown lairs; the palpi showing the former in preponderance upon the under side, becoming pallid on the basal joint beneath; antemae black-brown above, clay brown externally beneath, the naked crook fusco-castaneous.

Wings above black-brown with a chocolate tinge, the fringe mostly of the same, but interrupted, especialy upon the upper half of the hind wing, with sordid white. Fore wings with a broad, mesial, transverse, psendo-vitreous belt of amber, with a golden reflection, extending from the costal edge just before the middle, toward but not quite to the imner angle, stopping short at the submedian nervure; its interior border is uearly straight, its exterier less regular, showing a broad, arcuate excision above the middle median nervule, at which it broadens suddenly and is then convex to its bluntly rounded termination; midway between this beit and the apex of the wing is a small, silvery white, ritreous, straight bar depending from the costal margin, broken by the nervure into three subeqnal spots and generally followed at its onter lower corner by a contiguous minute spot.

Beneath, all the wings brown, with ferruginons and castaneous clouds, the fore rings marked as above, only that the broad band is white above the subcostal nerrmre, and has an indistinct, powders limit at its lower extremity, where it reaches almost or quite to the imer margin; apex of the wing clonded with ferruginous and blackish brown, the latter in irregular and rague transrerse markings, subparallel to the outer margin. IInd wings crossed by two not rery distinct, rich, dark brown belts, one pre-mesial, the other extra-mesial, dividing the wing into thirds; they are both broad, with irregnlar borders, stopping short at the submedian nerrure; a similar but often subobsolete uarrower belt, composed of contiguous and confluent lunules, is fomed just prerious to the outer margin, often rendered more conspicuous by a pordering of bluish white scales, which bring it into relief; at other times obscmed by a corering of similar scales, and always indicated to a certain extent by paler lunulate intervals between it and the extra-mesial baud. Expanse of wings, $43-5 \pm \mathrm{mm}$.

Caterpillar. Last stage. Head black, with a large, bright orange spot at the front basc of each hemisphere, lying at the bottom of a large, pale lavender spot, which corers more than half of the front. Body green, with a slender, darker green, dorsal live, a broad, pallid, stigmatal stripe, above which the sides are obscured with darker green; dorsal thoracic shield narrow, equal, black, the part of the segment in front very pale bromish yellow, like the legs and under surface. Length, 36.5 mm . Described from the figure by Boisduval and LeConte.

Chrysalis. Uniform pale yellowish brown, the incisures dusky. Length, 24 mm .; height, 5 mm . From Boisduval and LeConte.

This is a southern butterfly, oceurring throughout the southern states from Georgia to Arizona, and as far north as West Virginia and Kentucky. It does not seem to be so common as the other larger Hesperidi of the same region, and Abbot expressly calls it rare. It occurs also in Mexico, as I have specimens from Putta, about 150 miles from Oaxaca on the Pacific slope.

Abbot bred the butterfly on April 25th, from a caterpillar which shut
itself up in its eocoon three weeks previonsly，and Maynard collected a spee－ imen in Tillahassee，Fla．，April 17．Nothing else is known of the seasons of the insect，which Abbot says frequents the sides of swamps．In his varions manuseripts Breweria afuatica，one of the Convolvulaceac，is given as the food plant of the caterpillar，and uron this it is figured by Boisdu－ val and LeConte．

## THORXBES SCUDDER．

## THORYBES ELECTRA．

## Euctamus electra Lintn．，Can．eut．，xiii ：63－60（1：81）．

Imago．Front of head dark brown．Locklet black，curving about half way over the ejes．Antemaae about half the length of the anterior wings，clark reditish brown， marked inwardly with white at the joints，expandiug rapidly into the elnh（the ter－ minal half of the club lost）．Palpi in length about equal to the diameter of the eyes， clothed with thick，bristly，dark brown lairs，some of which are white tipped；apical joint short，conical，projecting a little beyoncl the hair－

Thoras above and beneath elothed with long，brown hairs，concolorons with the posterior wings．Legs dark brown；the posterior pair have the femur and tibia of the same length，bearing brown hairs which nearly equal them in length；tibiae armed with two pairs of spurs ；tarsi twice as long as the tibiae，moterately pinose．

General color dark brown，approaching that of pylates；the fringe concolorons with the terminal portion of the wings，a little paler at their tips．Size of small ［Thanans］juvenalis．Primaries narrower than in［Thorybes］pylates Scudd． 9 ，more rounded on the costa，and more oblique on the hind margin．Primaries with eleven transparent white spots，upon which an ordinary lens shows regular rows of small black scales，the spots as follows：near the end of the cell（apparently open）are two spots，separated by the cellnlar fold and extending to the enclosing veins（subdorsal and median），the mper one twice as large as the lower＇，and prolonged backward supe－ rionly in one or two teeth，the lower one subtriangular in shape；abore and in line with these two，in cell 10 ，is a small，clongated spot，the smallest on the wing，while beneath them and in range，in cell 2 ，exteucting from vein 2 to vein 3 ，is the largest spot on the wing，enlarged superiorly and exeavated inwardly．Outside of this discal band of fom spots，are seven others，bordered by clark brown，and arranged in an irregular curve，as follows：in cells 9,8 and 7 ，three costo－apical spots，olligue to the costa； outside of these，in cell 6 ，a spot；in cell 5 ，still nearer the margin，another； in cell 4 ，a little further remored from the margin，another；these last three sub－ triangular in shape；in cell 3 ，exteuding from vein to vein，a subruatrate spot， placel farther from the margin，about equidistant with the lower costo－apical spot；these seren spots，commencing at the costa and omitting the tlfth，show a regu－ lar increase in size．Outside of these transparent spots is a series of obscure，clark brown，intra－nervular，subterminal spots，which merge into the dark brown shade of the margin．Inside of these spots，the wing shows by oblique light a purplish reflec－ tion approaching a grape bloom，but more vivid，with the exception of the internal margin and two brown bands of the color of the outer margin and posterior wings； the bands extend from the subcostal to the intemal rein；the outer and broader em－ braces the discal band of transparent spots in its outer margin，ancl the other crosses the median vein at its intersection by vein 2 ；a brown shate rests also on the base of the wing．The costal rein of the primaries intersects the costa nearly opposite the end of the cell；vein 8 reaches the margin at the extreme apex，not below it．Secon－ daries rounder，not prolonged at the anal angle as in pylales，nor excavated opposite the cell as in most［species of Thanaos］．Seconclarics traversed，at about their outer
third, by a namow, nbsene brown band, insile of which the wing is chark brown ; ontside of thi band, the subterminal serie, of brown spots of the primaries is continued.

Bencath, the purplish reflection of the upper surface appeare only at the tip of the wing, the median and basal portions being dark brown, concolorou- with the secondaries inside of the pale brown band; the obscure, intra-nervular brown spots of the upper surface are repeatel and contiuned on the secoudaries; the transparent spots are without the lines of brown seales.

Ablomen darker brown, reaching only to the pale band of the hind wing-. Expanse of wings. 42 mm ; length of borly, 8 mm .

The abore description is that given br lintuer, with only such transposition as to make it agree with the order followed in the present work.

All that is known regarding this butterfly is the statement by Mr. Lintner that one specimen "was captured in Hamilton, Ontario, by Mr. J. Alston Moffat, in 1877, in company with another like it. which escaped capture. It is presumed to belong to Thorybes.

## PHOLISORA SCLDDER.

## PHOLISORA HAYHURSTII.

| Ifesperid hayhustii Elw., Trans. Am. ent. soc., iii: 22 (1970). <br> Nisonindes hayhurstii Kirb., Syn. cat. Lep., 631 (18:1). <br> 1holisnra hayhurstii Scudd., syst. rev. |

Ihelios hayhurstii Hew., Cat. coll. diurn. Lep., 239 (1559).
tholismed hayhurstii Scudd., syst. rev.
Imago. Head and upper surface of palpi tufted with black and saffron scales, the former predominating; the palpi sordid white beneath; antennae blackish brown with clay brown under surface.

Wings dark ashen brown, enlivened by three sets of parallel arcuate bauds of rich flark brown, one narrow and submarginal, the other tro diriding the wiugs subequally, broad above and narrowing below; the middle of the three is the broadest and on the upper half of the wing much broader than the width of the cell; these bands are all obscure and cloudy, and in addition the wing is occasionally flecked very sparsely iudeed and indiscriminately over the whole surface with pale bluish white scales. Qu the fore vings, depending from the middle of the outer half of the costal margin, are two minute silvery white spots often reduced to the merest dots in the superior subeostal interspaces; and there is occasionally present a similar dot, easily overlooked, near the base of the lower median interspace at the inner edge of the middle band. On the hind wings the transrerse markings are narrower and generally more obscmre, the midhle band sometimes no broader than the others.

Beneath, nearly uniform dark gray brown, the outer third of the wings a very little lighter, all the wings obscurely mottled rith slightly darker and lighter markings in whick no clefinite patteru can be cliscovered, excepting occasionally with the ntmost ragueness a repetition of the darker markings above; the white dots of the fore wing are sometimes present also below. Expause of wings, $26-30 \mathrm{~mm}$.

Egg. Broadly arched, the ribs very thin, about .1 mm . apart, .08 mm . high at highest, the cross lines frequent and straight, forming betreen them aud the ribs quadrangular cells .025 mm . high, and .083 mm . broad, the surface profusely punctured With a remarkably uniform distribution, the punctae themselves being very miform in size, about. 0025 mm . in diameter and circular. Height of egg, . 48 mm . ; diameter, . 69 mm . From specimens in glycerine.

Caterpillar. Firststage. Head blackish castaneons; clorsal thoracic shield pale castaneous, the posterior edge blackish. Borly white with a yellowish tinge. Legs and prolegs concolorons. Length, 1.5 mm ; breadth of head, 4 mm . From specimens in glycerine.

Second stage. Head black; dorsal thoracie shield blackish castaneous; body pale greenish yellow, all the legs and prolegs concolorous. Length, 2.15 mm ; breadth of head, .55 mm . From specimens in glyeerine.

Third stage. Colors as before. Length, 4.5 mm . ; breadth of head, . 55 mm . From speeimens in glycerine.

Fourth stage. Head black, densely elothed with delicate pallid hairs. Dorsal thoracie shield fusco-eastaneons. Body green, the legs and prolegs concolorous. Length, 8 mm . ; brealth of head, 1.75 mm . From specimens in glycerine.

Last stege. Head piceous, seabrons, including near the middle of the front of each hemisphere some slightly larger, piceous and smooth tubereles, the pile pale brown. Dorsal thoracic shield testaceous, paling behind. Body green, corered with the minutest possible papillae in the centre of small, eircular bits of tongher integnment, and bearing the minntest fungiform colorless bristles. Legs and prolegs concolorous. Spiracles testaceous. Length, 25 mm ; breadth of head, 2.75 mm . From blown specimens.

Chrysalis. Uniform pale castaneous, glistening, with no bloom, the apical third of the wing cases more or less blotehed or discolored with fuliginous tints; rim of the prothoracie spiracle black; cremaster very dark castaneons above, apically blackish fuseous, the hooks luteo-eastaneous; hairs of body rather abundant, long and pale fulvous. Length, 14 mm . ; breadth, 4 mm . From dried specimens.

This butterfly inhabits all om southern states as far north as West Virginia and Maryland on the Atlantic coast, and west to Kansas and New Mexico.

Nothing is known of its scasons, excepting what I can give from notes furnished by Dr. William Wittfeld of Brevard Co., Florida. He obtained eggs on pigweed, presumably Chenopodium, Jnly 25 ; these hatched in four days and the successive moults were passed August 2, 5, 8, 13, and the chrysalis was formed August 22, the duration of which is not stated. Evidently, then, there must be several broods a year. The eggs, according to Dr. Wittfeld, are always laid on the upper side of leaves; when irritated or in self defence, the full grown caterpillar ejects a greenish fluid from its mouth. The butterfly flies low and almost always in the woods, though it feeds at the edges of the same; excepting this, it is seldom to be found in open ground; it feeds or suns itself, alike on a leaf or on the ground, with spread wings.

## TRIBE PAMPHILIDI.

## OARISMA SCUDDER.

Oarisma* Scndd., Syst. rev. Amer. butt., 54 (15\%2). Thymelieus pars Auctornm.
Imago. Head broad, exceptionally depressed. Front transverse, three times as broad as high, slightly, broadly and roundly emarginate below, the lower outer angles strongly excised, slightly and uniformly tumid, surpassing considerably the front of the eyes. Whole vertex raised above the eyes, though flat, the eyes being set low. Anteunae in slight depressions, very distant, being separated by four times the diameter of the basal joints, very short, being seareely half as long as the elongated abdomen, and hardly more than a third as long as the fore wings, composed of about thirty-one

[^12]joints, of which about seventeen form a large and long, depressed, eylindrical club, comprising about two-fifths of the whole antenna, increasing very gradually in size, and bluntly roundel at apex, four or five naked joints entering into the diminution of size, with no sign of a crook; its stoutest part is just before it begins to taper, where it is about three times as stont as the stalk, and the joints are about four times as broad as long; on the stalk they become hardly twice as long as broad. Palpi very stout but pretty long, the apical joint very slender and elongated, porrect; the midille joint alone is as long as the eye, cylindrical and stout, being about four times as long as broad and nearly straight, the apical joint not mneh shorter, very slencler, tapering to a fine point at base, not more than a fonrtl as broad as the middle joint.

Wings ample, the fore wings triangular, about two-thirds as long again as broad, the lower outer angle falling not much within the middle of the onter half of the costal margin ; costal margin straight beyond the basal areuation; outer margin straight, excepting at the roundly angulated tip. Cell nearly two-thirds the length of the wing; third superior subcostal vein arising at about the middle of the wing. Hind wings triangular, with gently and regularly areuate outer margin, the inner and costal margins of about equal length. Subcostal fork arising slightly nearer the base than the first subcostal fork.

Fore legs very small. Fore femora fully as long as the hind femora, a little longer than the fore tibiae; the latter not much longer than first joint of fore tarsi, and with an exceedingly small epiphysis; first joint of tarsi as long as the three following together. Hind tibiae about a third longer than hind femora, and about two-thirds as long as the tarsi, with two pairs of spurs; first tarsal joint considerably longer than the remaining joints together. Claws minute, very strongly arcuate, the paronychia forming a simple, equal, curved, round-tipped lobe beside and below it, of the same length.

This genus of stiff-looking skippers is composed so far as known of only a couple of forms, differing only in their size and the extent of the markings; they occur in the eastern Roeky Mountain region and castward to the Mississippi valley, between latitucles $38^{\circ}$ and $50^{\circ}$. They are simply marked with exceedingly short antennae and long club, and presumably belong to the first section of Pamphilidi as separated in this work, though nothing is known of their earlier stages. The butterflies appear on the wing once, in early summer.

## OARISMA POWESHEIK.

Hesperia powesheik Park., Amer. ent., ii: 271-272 (1870).

Oarisma poweshieh. Seudd., Syst. rev. Amer. butt., 54 (1872).

Thymelicus poweshiek French, Butt. east. U. S. 301 (1886).

Thymelicus poweschieh Elw., Cat. diurn. Lep. Amer., 67 (1884).

Thymelicus garita pars Edw., Cat. Lep. Amer., 49 (1877).
Ancyloxypha garita pars Streck., Cat. Amer. Maerolep., 175 (1878).

Figured by Glover, Ill. N. A. Lep., pl. Q. fig. 3, ined.
[Not Hesperia garita Reak.]

Imago. Head tufted above with bright tawny hairs, mingled at the base with many black scales, especially posteriorly; under surface of palpi with silvery white scales through which pass many black hairs; antennae bright tawny, the under surface of the club pallid ; thorax covered with mingled brown and tawny bairs, beneath with dull silvery scales and white hairs; the femora and tibiae the same, excepting that the upper surface of the tibiae is very dirty yellow, as also nearly the whole of the tarsi.

Wings above rich dark brown with mnlberry reflections. Fure avings heavily marked with bright golden tawny along the whole costal margin as far clownward as the cell
and ncarly to the apex of the wing, narroring apically; scales of the same color often line and narrowly mark the nervores, especially the median in it, upper fieldand the snbmetian, occasionally also flecking the imner border. Ifind rings enlivened only by long, olivaceous, tawny hairs which cover profnsely the basal third or more of the wing; fringe dark gray from a heterogeneons mingliug of scales of many color, especially pallid and fuliginous.

Beneath : fore wings very dark brown, the costal border broadly margined with very dull, mingled pallid and dull tawny scales, the former preponderating next the costal etlge itsclf ancl also found marking all the nervures, even those which cross the tark brown parts of the wing ; the outer margin in the subcostal and median region rather broadly and rery heavily flecked with similar scales. Ifind wings with the basal color of the same dark brown as the fore wings, but above the midale of the medio-submedian interopace very heavily flecked with white seales which always distinctly mark all the nervures and occasionally corer almost all the intervening interspaces; occasionally away from the nervures changing to a pale rellow, a color which edges the costal margin in its basal half. Expanse of wings, $31-3 \pm \mathrm{mm}$.

This is a westem butterfly, occuring in northem Illinois, Iowa and Nebraska, and also in Dakota, and according to Edwards in Montana and Colorado, though it may perhaps be questioned whether the neighboring O. garita be not here mistaken for this species, though Mead says it is not garita but perhaps a variety of powesheik which is found in the Yellowstone region of Montana. It flies in Iowa, Nebraska, and Dakota at the end of June according to Parker and Dodge, but nothing further is known about its history.

## POTANTHUS SCUDDER.

Potanthus* Scudd., Syst, rer. Amer. butt., 54 (18i2). Pamphila pars Auctorum.
Imago. Head large, unnsually broad. Front but little tumid, nearly four times as broad as ligh, but little, and only below, advanced in front of the eyes. Eyes large, moderately full, circular, naked. Antemae separated at base by much more than the face-breadth of the cyes, much longer than the abdomen, the slender stalk consisting of abont twenty joints, the longest in the midule five times as long as broad, the club gradually and regularly incrassated (but incomplete in all specimens seen).

Fore wing slightly more than half as long again as broal, the lower outer angle falling well beyond the middle of the costal border; costal margin tolerably straight, except at base and extreme tip; outer margin gently convex. Costal nervure searcely so long as the cell ; third subcostal nervule arising hardly beyond the middle of the wing; cell a little less than two-thirds as long as the wing, fully five times as long as broad; first median nervule arising midway between the base of the wing and the second nervule, and rery far before the origin of the first subcostal nervule. Hind wing well romnded, not elongate, ouly a very little longer than broad; outer margin regularly convex. First median nervule arising but little nearer the base than the subcostal fork.

Middle tibiae abont five-sixths the length of the middle femora, and not greatly longer than the first tarsal joint, armed at tip with a pair of exceedingly long and slender spurs; first joint of tarsi as long as the next three together, the last joint no longer than the fourth, all armed beneath rather feebly with delicate, recumbent spines. Claws mimute, strongly arcuate, no longer than the thickness of the joint. Paronychia inferior, lateral, even slenderer than the claw, slightly shorter, a little arenate, hardly tapering.

* $\pi i v \omega$, ävos, one that drinks at a flower.

The only specimen- at hand of this genu, being imperfect, I am mable to chatacterize it as fully as I should otherwise have fone. Still fewer points could have been tonched upon, but for the generosity of the liev. Dr. LIolland in lending me the type of Ilesperia omaha.

This is a small group of Pamphilidi composer of three or four species, all of which appear to be very rare, and alnost nothing is known to me of their distribution and nothing of their history. They oceur in western America from California and Colorado to, or nearly to, the Isthmms of Panama, and have also been taken on the Atlantie slope in the middle United States. They resemble not a little certain Anstralian types, but I have not been able to make a suffieient study of their strueture.

## POTANTHUS OMAHA.

Hesperia omaha Edw., Proc. ent. soc. Philat., ii : 21 (18ti3).
Potanthus omahe Sculd., Syst. rev. Amer. butt., 54 (1572).

Carterocephalus omaha Edw., Cat. Lep.

Amer., 49 (1877) ;-French, Butt, east.U. S., $300-301$ ( $15 \times 5$ ).

Hesperia mingo Eilw., Proc, ent. soe. Philat., vi:20: (186if).

Imago. Head covered above with tawny and black hairs intermingled, tawny only in frout; antennae blackish brown, annulate with tawny beneath, the whole under surface and the apical half of the club tawny.

Fore vings tawny, marked with very dark maroon brown; there is, especially, a long aud broad, longitudinal belt, following the under surface of the median nervure as far as the tip of the cell, and jnst not reaching the inner border next the base; at its npper outer limit it is overlapped by another longitudinal belt oecupying the base of the interspaces beyond the cell, infringing slightly upon the cell itself, and covering two-thirds of these interspaces; at its upper interior limit there is, confluent with it, a ray or triangular patcle directed mpward to the costal marcin, which itself is marked more or less heavily with dark brown; besides there is a slender yay of the same color following the subcostal margin halfway across the cell, and the outer margin is marked with brown in various breadths; in the upper subcostal interspace the marking runs nearly halfway to the extremity of the cell; in the interspace beyond the cell it is not more than an interspace in width; below this it increases steadily in width by as much as the interspace is broadened, and the interior limit is here lunulate; there is practically thas left a clark brown wing with three large patches of tawny: a small, triangular patch near the apex, a longitudinal belt along the costal margin, and an oblique, extra-mesial, transverse belt. Ifind winys with the same colors, mostly clark brown, with a small, circular, tawny spot in the cell opposite the firstsubmedian forking, and a straight, but irregular, broad, transverse belt just beyond the middle of the wing, which broalens in the median interspaces and rums from the middle of the outer half of the submedian nervure to the last subenstal nervure, where it just fails of reaching the margin of the wing, in the subcostal interspaces being marked only by slight points; there is also a dash of tawny in the costo-subcostal interspace opposite the spot in the cell.
Beneath, the tawny markings of the upper surface are repeated throughout and are rendered more conspicuous, because the dark brown of the wings is heavily flecked with tawny scales, excepting along the ellges of these markings, which brings them into greater relief, and excepting also in the lower half of the fore wings, where in the portion covered by the hind wings the dark markings are inky brown. Expanse of wings, 26 mm .

This species has been regarded by some as identical with $P$. californicns, but in the latter species the markings of the under surface of the hind wings are far less diver-
sified, the transverse, light colored band being indicated only by the dark and obscured edgings; and the upper surface of the fore wings shows on the costal margin a large, blackish brown, longitudinal bar on a line with and as large as the extra-mesial, tawny band.

Very little is known of this butterly, which has been taken only in West Virginia and Colorado.

## ERYNNIS SCHRANK.

## ERYNNIS UNCAS.

Hesperia uncas Edw., Proc. ent. soc. Philad., ii : 19-20. ju. 5, fig. 3, 2 figs. (18fie).<br>I'amphila uncas Kirb., Syn. cat, diuru. Lep., 600 (1871); French, Butt. east. U. S., $308-209$ (1886).<br>Anthomaster zncas Scudd., Syst. rev.

Amer, butt., 57 (1872).<br>Hesperia ridingsii Reak., Proc, ent. soc. Philad., vi : 151 (1866).<br>Ocyles ridingsii Mead, Wheeler's report, v: 788 (1876).

Imago. Head tufted above with dull olivaceous and black hairs, the apical joint of the palpi black, the under surface of the palpi pallid; antemnae black, heavily fleeked beneatl with white, excepting at the naked tip of the elub, which is more or less enlivened with castaneous. Thorax covered above with dull gray, olivaceons hairs, beneath with dull, silvery white seales and whitish hairs; the legs elay brown.

Wings above rather clark slate brown, varying in depth of tint, and with glossy reflections. Fore wings usually marked with pallid, occasionally with tawny spots, of which there is a pair of confluent ones marking the extremity of the cell. and an extramesial series of spots forming a very irregular, oblique, subcontinuous band; it is composed of three elongated spots in the subcostal interspace, midway between the tip of the cell and the wing; a pair of subquadrate spots in the interspaces berond the cell whose inner border is on a line with the outer border of the neighboring spots, and, obliqnely continuous with these, three very umequal spots in the median and medio-submedian interspaces, that in the lower median interspace generally the largest, that in the medio-submedian very variable and more frequently fulvous to a greater or less extent, occupying the middle of the interspace; these spots, especially the latter ones, are most conspicuous in the female; in the male they are nsually much reduced in size and those in the lower median and medio-snbmedian interspaces are subobsolete and in part obscured by the fulvous tone of all that portion of the wing which follows the diseal stigma; this is composed very much as in its ally E. metea. Mind wings more or less suffused with pale tamay, more conspicuons in eertain lights than in others, marked at the tip of the cell and crossed by an extra-mesial series of subcontinuous pallid spots, generally more or less tawny, which are the vague repetition of the more distinct spots of the under surface; fringe of all the wings sordid white, often more or less infuscated in the upper half of the fore wings and preceded by a thread of blackish brown.

Beneath, dull, dirty, olivaceons brown, a deeper olivaceous brown bordering all the markings, especially on the hind wings, and lending them greater perspienity. The fore wings show in both sexes the markings of the upper surface of the female, but they are perhaps more conspicuously continuous, and terminate on the inner border in a large, vague, triangular, pallid spot; these show also a slight tendency to follow as threads down the nervures, and oceasionally the outer half of the wing apart from them is heavily flecked with sattron scales. On the hind wings the extra-mesial band is very marked and almost invariably continuons, forming a bent band, beut at somewhat ess than a right angle, composed of subquadrate spots, produced at all the augles along the nervure tips, and margined, externally at least, with dark brown, the upper
lalf of the band ruming from the costal nervure to the median in a straight liue, having a direction from the miatle of the costal border to the tip of the upper median nervule, the lower half in a direction from the outer angle of the wing to the middle of the inner margin; there are besides two spots within this: one at the lower apex of the cell, the other at the extreme base of the costo-subcostal interspace, the latter sometimes subconfluent with the outer spot of the same interspace; all these spots are dull, silvery white. Expanse of wings, 31-37 mm.

This butterfly has been credited to a wider range of territory than can perhaps be claimed for it, though it is certainly found from Pemnsytvania to Colorado. As the species of this genus are difficult of separation unless considerable series are at hand for comparison and for the study of the abdominal appendages, determinations by those who do not make use of these means must be taken with qualification. It has been given as inhabiting the Rocky Mountain district from Dakota to Arizona. Nothing is known of its history, except that Mead found it in Colorado at Twin Lakes in July, "generally upon or ncar the dwarf lupines, which grew with bunch grass and low herbage, in open spaces between the plants of sage brush."

## LIMOCHORES SCUDDER.

## LIMOCHORES PALATKA.

Hesperia pilatka* Edw., Trus, amer, ent. Pamphila dion Edw., Can. ent., xi:233soc., i: 287 (1867).

Limochores palatke scudc., Syst. rev. Amer. butt., 29 (1872).

Pamphila bulenta Streck., Cat. Amer. macrol., 170-171 (187S).

Ifead densely tufted above with tawny and black-brown hairs, which also cover the apical face of the palpi, excepting the apical joint which is wholly black-brown above, tawny beneath; rest of palpus covered with white scales like the head behind and beneath the eyes, gradually merging into tawny. Antennac black-brown above, amulated with tawny, beneath almost wholly tawny, the apical naked portion of the club, including the crook, orange castaneous. Thorax covered above with tawny, greenish yellow and pale green hairs; beneath with sordid pale greenish yellow; the femora tawny but purple at tip and on the lorrer portion of the anterior side; the tibiae and tarsi dull tawny, the latter infuscated apically.

Wings above black-brown, heavily marked with tawny, hariug in the males a decided gleam; in the fore wings of the female the brighter colors are mostly contined to an extra-mesial, curving, bent band broadened from above downward, bent in the interspaces beyond the cell, consisting of longitudinal spots clearly interrupted by the nervures, starting from the middle of the onter half of the costal border aud euding with its interior edge at the middle of the submedian nervure; in addition the apical half of the cell is more or less sutlused or streaked with tawny which is u-ually of a paler color than in the male. In the male the tawny oecupies almost the entire disk excepting the infuscated, more or less strigate base and reaches as far toward the outer border as would correspond to the outer limits of the extra-mesial belt of the female, the onter black-brown bordering being of subequal width and of an average width of two interspaces; sometimes, and especially in northern specimens, the

[^13]costal border is more or less infuscated; the discal stigma consists of two moderately broad bars of velvety black, the upper and onter at the extreme base of the lower median iuterspace, following the median nervure, the lower and inner con. nected with the lower inner corner of the upper at its own upper outer corner, and traversing the medio-submedian interspace in a line nearly parallel to that of the upper portion of the stigma, but bent in the least possible degree downward; the two portions of the stigma are equal and each rounded at either end and about three and a half times longer than broad with slight individual variation. Hind wings with the disk more or less marked with fulyons tawny in the centre, leaving an extremely broad margin aronnd the whole, and invariably cut distinctly by blackish fuscous nervules; it is occasionally reduced almost entirely to a single longitudinal ray in the subcosto-median interspace, where, when best developed, it is almostalways more distinct than elsewhere, and extends from the apex of the cell more than half way to the margin of the wing; the whole disk of the wing is, moreover, heavily clothed with dark tawny hairs; fringe pallid, mixed with brown scales which nearly supplant the paler ones on the upper half of the fore wing.
Beneath dark brown, more or less enlivened with a sprinkling of tawny scales. Fore wings sprinkled with tawny scales having more or less of an orange tinge, especially above the median nervure, beneath which, previous to the extra-mesial band, which is less couspicuously repeated beneath in both sexes as in the female above, the wing is deeply infumated with blackish or blackish brown, which also follows the inner margin nearly to the tip and suffuses more or less the apical half of the median and submedian interspaces in both sexes, though the latter more commonly in the male than in the female; outer margin marked with a black brown thread and the fringe concolorous with the wing or a little more pallid on the lower half. Hind wings having the same general color as the upper half of the fore wings, exceptiug that a broad longitudinal belt of yellow tawny follows the subcosto-median interspace from the extremity of the cell more than half way to the margin, beyond which it gradually fades out, and another the whole of the medio-submedian interspace from base to margin, while the inner margin beneath this is slightly yellower than the main ground color; in addition the veins are frequently marked with yellow, but this feature is more common in northern individuals than in southern, those from Florida being frequently almost uniformly flecked with fulvous scales throughout, showing little or no sign of the broad yellow rays or of any distinction of nervures. Expanse of wings, $\delta, 39-44 \mathrm{~mm}$. ; ㅇ, $42-49 \mathrm{~mm}$. Described from 5 §, 5 ㅇ.

I judge that the description of the caterpillar referred to this species by Chapman does not belong to it because I have received from him named specimens of the imago from Florida which do not belong to this species but to an allied one which is intermediate between Limochores pontiac and Limochores arpa, sent me many years ago by Mr. Edwards under the specific name of pallas, but which has never been described under that name. Specimens of dion, kindly sent me by Professor Frencl, compared with specimens from Florida, which had been compared at the time of its description with the type of Edwards's palatka, show them to be the same species.

The distribution of this butterfly is evidently little known, since it has been found only in the western Mississippi states - eastern Nebraska, northern Illinois and Indiana-and at Hamilton, Ontario, and then in northern Florida. Nothing is known of its earlier stages.

## EUPHYES SCUDDER.

## EUPHYES OSYKA.

Hesperia osyh Edw., Trans. Am. ent. soc., 345 (1886).<br>1:288 (1867).<br>Euphyes osykic Scudd., Syst. rev. Amer. butt., 59 (1872).<br>Lep., 607 (1871) ;-French, Butt. east. U. S., Hesperia baeis Boisd., MS.

Imago. Ilead tufted above with bright saffron hairs, interrupted behiud the antenuae by a transverse belt of black-brown scales; basal half of the palpi silvery white, apical half saffron, mingled above with many black scale-hairs, the apical joint black; antennae black above, annulate with clay-brown beneath, the basal half of the club beneath clay-brown, the naked tip brighter. Thorax clothed above with brown scales and hairs of rarions depths of color, mingled with many greenish hairs, bencath sordid white; the legs dark clay brown.

Wings above uniform dark blackish brown, with a very slight tawny gloss. Fore wings with a pair of small, pallid spots, a sinall, roundisl spot at the extreme base of the upper median interspace, and another larger than it in the interspace below removed a little toward the base; these spots are larger in the female than in the male, and are accompanied in the latter by a row of two or three miunte dashes of the same color, depending from the middle of the outer half of the costal border.

Beneath, uniform dark brown, with a purplish tinge, the lower half of the fore wings with a slight tawny tint; the markings of the upper surface are repeated, generally a little more distinctly. Expanse of wings, $28-31 \mathrm{~mm}$.

This butterfly belongs to the Gulf States, where it has been reported from South Carolina and Georgia on the east, to Louisiana and Texas on the west; but as it has also been taken in northern Indiana, it must be found over a larger extent of territory than had been supposed.

Nothing whatever is known of its history or habits.

## PRENES SCUDDER.

Prenes * Scudd., Syst. rev. Amer. butt., 60 (1872). Pamphila pars Auctorum.
Imago. Head broad, the front four times as broad as high, greatly excised laterally below, uniformly and considerably tumid, surpassing somewhat the front of the eyes. Vertex almost uniformly tumid with the front, and almost as considerably rising above the upper level of the eyes, with a transverse, coronal carina, slight and short, in the middle of the summit. Eyes large, full, circular, naked. Antennae inserted in shallow depressions, greatly separated, the space between equal to the whole height of the head, slender, of about the length of the long abdomen, composed of about thirty-eight joints, of which about half form the club, which is not more than half as long as the stalk, rery gracefully elongate fusiform or Indian-club shaperl, with a greatly attenuated, delicate, slender, tapering, pointed crook, composed of eight or mine joints, nearly or quite twice as long as the breadth of the club, and about half as long as it. Palpi short, the basal joints vely thickly clothed, so as to appear very
large, but in reality the middle joint is bullate, only half as long again as broad, the apical joint slender, small, not so long as the width of the middle joint.

Fore wings clongate triangular, the lower onter angle falling a little outside the middle of the costal margin, the apex pointed; costal margin full uext base, beyond distinctly thongh faintly and broadly excised; onter margin slightly sinnous, with a tendency to an angulate bend next the upper median nervule, and a faint excision in the lower median interspace. Second subcostal nervule originating before the middle of the wing ; sccond median nervule arising opposite a point between the origin of the third and fourth subcostal nervule; cell nearly two-thirds as long as the wing. Hind Wings triangular, the costal and imer margins of about equal length, the outer margin gently rouncled, but mesially excised a little, so as to appear faintly bilobed. First median fork slightly more distant from the base than the subcostal.

Fore femora and hind femora of equal length, the former half as long again as its tibia, the latter four-fifths as long as its tibia; fore tibia hardly two-fifths as long as the fore tarsi, which are only a little shorter than the hind tarsi; first joint of hind tarsi as long as the remainder together, the last joint as long as the preceding. Claws minnte, strongly bent in the middle, the paronychia simple, triangular, tapering lobes, as long as the claw and nearly concealing it on the side, but originating just below it.

This group of slender, sharp-winged and presumably very swift Pamphilidi is tolerably numerous in species, which occur from the southern part of the United States, through the Antilles, Mexico and Central America to Venezuela. Two species occur in the United States, both of which occasionally reach the northern balf. Nothing is known of their history or time of flight, excepting that on their northern edge they fly at the end of June.

## PRENES OCOLA.

> Hesperia ocol, Edw., Proc. ent. soc. Philad., ii: 20, pl. 11 , fig. 4 (1863).
> Pamphilh ocola Kirb., Syn. cat. diurn. Lep., 607 (1871); - French, Butt. east. U. S.,

332 (1886).
Prenes ocola Sculd., Syst. rev. Amer. butt., 60 (1872).

Imago. Head covered above with mingled fulvons and blackish brown seales and hairs, the palpi similar, pallid beneath at the base, the apical joint and the outer anterior edge black; antennae black, clay brown beneath, especially on the body of the club. Thorax covered with dull tawny hairs above, beneath with dull brown and pallid hairs; the legs dark brown above, dull saffron beneath.

Wings above uniform dark brown with a very faint, dark tawny reflection. The fore wings with very simple markings, consisting of a minute, triangular, vitreous spot at the extreme base of the upper median interspace, a much larger, strongly lunulate, snb-triangular, vitreous spot at the extreme base of the lower median interspace, its outer margin as far removed from the previons spot as its own length, and a faint, brief, longitudinal streak of the same, lying upon the middie of the submediannervure; in addition there is in the female a pair of very faint and minute dashes or dots close to the base of the last two superior subcostal interspaces, one directly above the other.
Beneath, warm dark brown; the base of the fore wings obscured with black, especially along the nervires; the markings of the upper surface of the female are repeated beneath in both sexes but the spot on the submedlan nervare becomes sordid white, and all the spots have a tendency to be of larger size, and in addition there is
sometimes found a minute dot in the lower part of the interspace beyond the cell in line with both the upper and the lower series. The hind wings occasionally show exceedingly faint traces of a row of faint light spots crossing the upper half of the wing just beyond the middle. Expanse of wings, $34-40 \mathrm{~mm}$.

The butterfly is found throughout the sonthern states, at least east of the Mississippi, and has also been found in the extreme northern part of Indiana and in eastern Pennsylvania, according to Edwards, so that it probably covers all the middle states as well.

We are entirely unaequainted with the life of the butterfly.

## PRENES PANOQUIN.

Hesperia panoquin Sculd., Proe. Ess. inst., iii: 178-179 (1863).

Pamphila panoquin Kirb., Syn. cat. diurn. Lep., 608 (1871) ;-French, Butt. east. U. S., 331 (1886).

Prenes penoquin Scadd., Syst. rev. Amer. butt., 60 (1si2).
Hesperia ophis Edw., Trans, Amer. ent. soc., iii : 216 (1871).
Hesperic cochles Latr., MS.

Imago. IIead covered above with mingled brown and black scales and tawny and black hairs; palpi with mingled white and yellow scales and near the extremity with many black scale-hairs; the apical joint black only above, elsewhere clay-brown; antennae black-brown beneath with a line of clay-brown, the naked portion of the club very dark castaneous. Thorax covered above with greenish brown scales, tawny and brown hairs ; beneath with dirty yellow hairs; the legs brown, more or less flecked with dull yellow, the tarsi darker above and paler beneath.

Wings above dark brown, somewhat variable in depth; when freshest, with a faint tawny reflection. Fore vings with a few small spots, usually pale dull yellow in the male, pallid in the female; there is a mere dot at the extreme base of the upper median interspace, a roundish, occasionally triangular spot near the base of the lower median interspace, midway between the previous spot and the extreme base of the interspace; also on a line with these there is sometimes found, more frequently in the $q$ than in $\delta$, a dot in the lower portion of the interspace beyond the cell, these three spots forming a single straight line in which they are equidistant; in rare instances there is in the female another dot in the upper portion of the same interspace beyoud the cell on a line with the previous and subconfluent with the other in the same interspace; the female also shows a pair of short dashes in the subcostal interspace in the middle of the outer half of the wing, the upper the outer, and there is also within the cell at its lower outer extremity, subjacent to the spot in the lower median interspace, a short slender streak, while a similar and generally larger streak rests upon the submedian nervure, as far from the margin as the spot in the lower median interspace; these latter markings are often obsolete, especially in the male. The hind vings occasionally show the mark of the longitudinal streak of the under surface.

Beneath, rather paler than above; all the nervures of the hind wings marked in very pale yellow, which is also the case to a less extent upon the fore wings, in the submedian nervure and the nervules of the apex of the wing, which are narrowly marked. Fore wings with the markings of the upper surface of the female repeated beneath, generally with greater clearness and completeness. On the hind wings there are two conspicuous, long, white, longitudinal dashes, one in the interspace beyond the cell, running from its termination at least half way, sometimes three-quarters, to the outer margin; the other in the medio-submedian interspace from the extreme base
to the middle of the previous streak, following the line of the median nervure. Expanse of wings, $32-35 \mathrm{~mm}$.

This butterfly is a species known best from the southern Atlantic states from South Carolina to Fey West and Apalachicola, Fla. ; but it doubtless inhabits other parts of the south since the specimens upon which the species was originally based in all probability came from the vicinity of New Orleans. It has latterly been found in abundance by Aaron at Atlantic City, N. J.

We are totally ignorant of its life and early stages, excepting that Aaron found it in New Jersey the last of June and first of July.

# HYMENOPTEROUS PARASITES 

of

NORTH AMERICAN BUTTERFLIES.

BY L. O. HOWARD, WASHINGTON, D. (..

Why, here you have the awfulest of crimes For nothing! Hell broke loose on a butterfly ! Browning.-The Ring and the Book.

It was in March, 1887, when Mr. Scudder first wrote asking me to revise and extend the chapter on butterfly parasites written by Dr. A. S. Packard for his (Scudder's) book on New England Butterflies, but published under the title "Some Ichneumon Parasites of our New England Butterflies," in the Proceedings of the Boston Society of Natural History, Vol. XXI. I at once replied that I should be glad to attempt the task, and some little time was spent during the summer of 1887 examining Dr. Packard's types and other material sent me by Mr. Scudder. Learning, during a visit to Cambridge in the fall of 1887, that there was no immediate hurry for my manuscript, I postponed the work until the summer of 1888, and meantime corresponded with several gentlemen interested in butterflies, and brought together some additional material, which I have studied with that already at hand, and present the results herewith.

The larger part of the material which I have seen was sent me by Mr. Scudder. Some of it had already been studied by Dr. Packard, while the remainder had been subsequently reared by Mr. Scudder or his correspondents. Considerable material, both in the way of specimens and notes, was also placed at my disposal by Dr. C. V. Riley, from his old collection and from the collections of the National Museum and of the Department of Agriculture. Mr. W. H. Edwards has sent me a number of specimens with notes, and Judge W. B. Thomas of Athens, Ga., Mr. A. H. Mundt of Fairbury, Ill., and Mr. H. H. Lyman of Montreal, have all sent specimens and short notes. Professor Riley has kindly written for me the portion of the chapter relating to the important parasites of the Braconid subfamily Microgasterinae, as I felt that from his familiarity with these difficult forms he would do them infinitely better justice than I could my-
self. Mr. E. T. Cresson has also, with his eustomary kinduess, made certain determinations for me in the Iehnemnonidae, and has sent me copies of several of Holmgren's generic deseriptions which were not accessible to me at Washington.

The chapter may be appropriately begun with a tabnlated arrangement of the hosts from which parasites have been bred, plaeing opposite to eaeh species of butterfly the parasites whieh have been reared from it, and the reverse. The main objeet of the chapter is, of course, to enable the observer to identify any parasites whieh he may have reared from butterfly larvae or pupae, supposing them to have been reared before, and I would advise him first, by examining this list, to aseertain what parasites have been reared from the insect in question, and then to eompare the figures and deseriptions of these particular species with the speeimens he has reared. If he does not in this way satisfy himself, then let him run through the synoptical table of genera and the deseriptions of species whieh follow, and it will not be difficult to ascertain whether his observation is a new one.

## Analytical Table of Families.

Anterior wiugs with several closed cells.
Anterior wings with two recurrent nervures.........................ICIINEUNONIDAE.
Auterior winge with but one recurrent nervure............................BRACONIDAE.
Anterior wings alnost reinless.
Pronotum not reaching to tegulac.
. (HALCIDID.AE.
Pronotum reaching to tegulae

## Analytical Tables of Genera.

## ICHNEUMONIDAE.

First segment of the depressed, pedunculate abdomen bent towards apex.
Ovipositor hidden or only slightly exserted.
Abdomen of acute at tip, last ventral segment retracted.
Scutellum flat or convex, gradually sloping to apex.................... Ichneumon.
Scutellum gibbons, abruptly declivous behind........................ Hoplismenns.
Abdomen $\&$ obtuse at tip, last ventral segment not retracted...................Trogis.
Oripositor distinctly exserted.
Areolet incomplete.................................................................................
Areolet complete............................................................................ Cryptus.
First segment of abdomen straight.
Abdomen petiolate, compressed for at least posterior half.
Cubito-discoidal cell receiving both recurrent nervures......................... Ophion.
Cubito-discoidal cell receiving but one recurrent nervare.
Spiracles of metathorax oval or elongate.
Apical margin of clypeus truncate................................... Exochilum.
Apical margin of clypens acutely angled or pointed.................Anomalon.
Spiracles of metathorax round.
Areolet large, rbomboidal............................................... Mesochorus.
Areolet small.................................................................... Limneria.
Abdomen sessile.
Ovipositor arising from a ventral cleft..............................................
Ovipositor arising from apex of abdomen...............................................

## BRACONIDAE.

Mesothoracic sutures distinct ; marginal cell minute, remote from the apex of the wing........
Microdus.
Mesothoracic sutures invisible; marginal cell large, reaching apex of wing.
Wings with two subnarginal cells, the second confused with the third.........Apanteles.
Wings with three submarginal cells, the second more or less complete...... Microgaster.

## CHALCIDIDAE.

## PROCTOTRUPIDAE.

But one genus-Telenomus-is considered.

# FAMILY ICHNEUMONIDAE LEACH. 

Genus IChineumon Linn.

#### Abstract

Ovipositor lidden, or ouly slightly exserted; basal half or two-thirds of first abdominal segment slender, expanded at apex, its spiracles closer to apex of segment thau to each other; areolet pentangular ; mesonotum without parapsides; metathoracic spiracles linear or uarrowly oval; petiole of abdomen not depressed; if abdomen acute at tip, last veutral segment retracted; $\delta$ ventral segments $2-4$ with a longitudinal fold; scutellum more or less flat, or simply convex, and then gradually sloping to apex; metathorax rarely bispinose.

Table of Species.

## Ichneumon rufiventris Brullé. Pl. 88, fig. 1.

## Ichneumon hunterae Pack.

Ichneumon sp. Pack.
Ilead, thorax and petiole of abdomen black, rest of abdomen dull, brick red, sometimes reddish brown. Head black, with the orbits part way up broadly marked with yellow, forming lanceolate, triangular spots, with the slenter apex opposite the antennae. Base and sides of labrum yellow. Head wholly black in \&. Paipi brown. Antennae in $\delta$ black; in of black, with a white ring in the middle, abont four joiuts usually being white. Wings smoky-violaceons. Fore legs brown, pale brown in d. Basal three-fourths of femora blackish, legs dark brown in \&. Hind legs black, hind tibiae paler at base; hiud femora reddish at base. Thorax black, sometimes yellow spots on scutum. Length (average), 才, 12 mm ., exp., 20 mm . ; f, 15 mm ., exp., 28 nmm . (Adapted from Packard.)
[The following description of the colors was taken during life: Antennae blackish fuscons; the middle joints pale, but infnscated. Body piceous; abdomen very deep reddish orange, the belly tinged with yellow, the ovipositor infuscated; extreme base of the femora inconspicuously sanguineous. s. 11. s.]

This species seems to be a quite common parasité of Vanessa huntera and V. cardui. I have seen two specimens, one male and one female, from Mr. Scudder, one female from Mr. Lyman, of Montreal, and Dr. Packard records a female from Virginia, all reared from this species. Mr. Cresson (Trans. Amer. Ent. Soc., vi:173) also states that this specics has been reared from huntera. Professor Riley has reaved it from cardui, and Mr. Scudder has so recorded it in his article entitled "A Cosmopolitan Butterfly." Miss Caroline E. Huestis records it from cardui in the Canadian Entomologist for July, 1881. Mr. Scudder has also sent a single male, reared by Dr. Dimmock, from Aglais milberti.

This specimen mentioned by Dr. Packard as "Ichneumon sp.," is, as Dr. Riley states, I. rufiventris. The difficulty into which Dr. Packard fell concerning the white banded antennac and the black face, I have solved by
an examination of the specimen to which Dr. Packard referred, and which proves to be a female, and not a male as he supposed.

Mr. Cresson (Proe. Ent. Soc. Phil., iii : 179, 180) deseribes three varieties of this species, viz. : incertus, semicoccineus and californicus, differing ehiefly in the coloration of the legs.

## Ichneumon caliginosus Cresson.

Female.-Black, subopaque, deusely and finely punctured; clypeus shining with a few large punctures; antennae half the length of the body, black, the 10th to 15 th joints white above. Thorax densely and confluently punctured, with an abbreviated impressed line on each side of the mesothorax in front; scutellum rather flat, smooth and shining, with a large white spot occupying nearly its whole surface aud slightly iudented posteriorly; metathorax scabrous, the elcvated lines well defined, the central area large and transversely quadrate. Wings fuscons, uervure black, stigma piceous, areolet 5 -angular. Legs shiming black, inner side of the anterior tibiae and tarsi whitish. Ahclomen entirely black; the first segment broad and finely acieulate, the peduncle slender; basal foreas of the second segment deep and oblique; apical segments rather smooth and shining; oripositor subexserted, yellowish. Length, 12.5 mm .; expanse of wings, 23 mm . (Aclapted from Cresson.)

Mr. Sendder has sent me one female of this species reared from Basilarchia archippus September 5. The speeies has been captured in Canada, Colorado and Illinois.

## Ichneumon instabilis Cresson.

## Ichneumon tharotis Packard.

Female.-Black or ferruginous, rather robust; head slightly narrowed beneath, the anterior orbits more or less red or yellowish; sometimes the head is eutirely red, or the face and clypens are varied with brown and yellowish or reddish; antemac moderately long, not robust, generally fulvons at base, yellow in middle and black at tips, sometimes only fulvous with tips hlack, or black at base, then fulvous, yellow and black; third joint elougate, longer than the fourth, which is subequal with the fifth; thorax often entirely ferruginous or more or less varicd with ferruginons, sometimes black immaculate, except the scutellum, which is always yellow and polished; tegulae ferruginous, often with a reddish spot in front and another beneath; post-scutellum sometimes reddish; metathorax rugulose, the central area large and subquadrate; wings subhyaline, more or less stained with fellow, nervures brown, stigma pale honey-yellow; legs honey-sellow or ferruginous; the coxae, tips of posterior femora, of their tibiae and most of their tarsi black, sometimes the most part of the posterior legs is black; abdomen oblong-ovate, subconvex, slender at base, generally entirely ferruginous, sometimes the fourth and fifth segments above are black or fuscons, sometimes the second and third segments only are ferruginous, and sometimes the incisures of the segments are more or less blackish; beneath ferruginons or yellowish ferruginous, dusky or black at tip. Length, $10-12 \mathrm{~mm}$.

Male. -This scx is exceedingly variable in color, some examples being almost entirely yellowish ferruginous, and others almost entirely black. Head black, with the anterior orbits and all beneath the antennae yellow; antennae long, sleuder, black above and brownish or fulvous beneath, the basal joint fellow beneath; thorax gencrally black, sometimes more or less varied with ferruginous, and in one specimen the mesothorax has four abbreviated, pale vittae; sometimes the thorax is black, immac-
nlate, except the scutellum, which is always jellow; generally, there is a spot or a sutural live before the wings, and at spot or line beneath; the post-scutellum is often reddish; legs honey-jellow: the fore anterior cosae often more or less yellow or honeyyellow, sometimes black spotted with yellowish beneath; the posterior coxae are generally black, sometimes more or less ferrnginous, their trochanters generally balf black and half howey-yellow; sometimes their femora are entirely black, or half black, generally only tipped with black, rarely entirely honey-yellow, their tibiae tipped with black; the general color of the legs varies from lemon-yellow to ferruginous; abdomen depresserl, opaque, sometimes entirely yellowish ferruginons, but generally black, with the second and third, and sometimes part of the fourth segments ferruginous or yellowish ferruginons; the first segment is either entirely ferrnginons, or black tipped with ferruginons, or with two apical yellow spots; the second and third segments are entirely ferruginous, or yellow stained with ferruginous; the fourth is either entirely black, or black spotted with ferrnginous, or entirely ferruginous; the remaining seg. ments are generally black or brown, often more or less varied with ferruginons; several specimens have the second and third segments bright yellow and the rest black. Length, 10.5 to 14.7 mm . (After Cresson.)

This is a very variable species. The specimen described by Dr. Packard as Ichneumon tharotis was an extreme variety of the female. It was reared by Mr. Scudder, June 2, from Phyciodes tharos. Mr. Cresson records it from Canada, Maine, Massachusetts, Connecticut, New York, New Jersey, Virginia, Georgia and Colorado, but does not know its host. During July, 1887, a single specimen of a variety of the male was received from Mr. Scudder, with the statement that he had reared it from the chrysalis of Oeneis semidea.

## Ichneumon versabilis Cresson. Pl. 88, fig. 2.

Male.-Dull black; line on anterior orbits, face, clypeus, mandibles, labrum, palpi, scape beneath, anterior margin of tegulae, line before, another beneath, scutellum, sometimes a spot or line behind, dot on four anterior coxae and trochanters beneath, their knees, tibiae and tarsi, anterior femora in front, posterior tibiae and tarsi except tips, sometimes two dots or a line at tip of first abdominal segment, and the secoud and third more or less, all bright yellow; occasionally the base of second and third segments is margined with dull ferruginous, and the apical middle more or less varied with black, sometimes interrupting the jellow on third segment into two spots, and in one specimen these are reduced to mere dots, and the yellow on second segment interrupted medially by a black line; wings subhyaline; postpetiole aciculated; gastrocoeli large and deep; antennae more or less pale beneath; posterior femora sometimes pale at base. Length, 12 to 13 mm . (From Cresson.)

Of this species I have seen two specimens of a variety of the male. Both were sent by Mr. Scudder. One specimen was obtained in Vermont from Heodes hypophlaeas, and the other by Dr. G. Dimmock from Polygonia faunus. It is recorded by Mr. Cresson from Canada and the United States. Both specimens were accompanied by the chrysalids from which they had emerged, and in each case the chrysalis was decapitated.

## Genus HOPLISMENUS Gravenhorst.

Parapsidal furrows of mesoscutum indicated anteriorly; mesoscutellum strongly elevated, abruptly declivous behind; metanotum always bispinose, metanotal spiracles
long, oval. Arcolet of fore wings pentangular. More than half of first abdomiual segment slender, its spiracles much nearer to apex than to each other; gastrocoeli large but shallow. Abdomeu of $\%$ acute at tip, the last ventral segment retracted; § ventral segments two to four with a longitudinal fold.

Hoplismenus morulus (Say). Pl. 88, fig. 9.

## Ichncumon morulus Say.

Ichneumon calcaratus Provancher.
Black; face, clypens, scape beneath. and sometimes spot on scutellum, $\delta$, and annulus on flagellum, $i$, white or pale yellowish; tibiae and tarsi bright yellow; wings uniformly fuliginous. Length, $\delta$ of, 15 to 16.25 mm . (After Cresson.)

I have seen two speeimens of this insect, one male and one female. Oue was sent me by Mr. Scudder and was reared by Miss Pierce from the ehrysalis of Polygonia interrogationis at Cambridge. The other was sent me by Mr. H. H. Lyman of Montreal who reared it in August, 1875, from a chrysalis of Euvanessa antiopa, at Portland, Me. The parasite in issuing decapitates the chrysalis $(88: 16)$. Mr. Cresson records the species from Canada, Connectient, New York, New Jersey and Virginia.

## Genvs TROGUS Gravenhorst.

Mesonotum without parapsidal grooves; mesoscutellum strongly elevated, generally snbpyramidal; metathoracic spiracles oval. Areolet of fore wings pentangular. First segment of abdomen bent at apex, basal half slender, apex much expanded, spiracles closer to apex than to each other; base of second segment with lateral pits (gastrocoeli) ; $\circ$ abdomen obtuse at tip, ovipositor hidden; the last rentral segment but slightly retracted, ventral segments four to eight smooth, llat, without longitudinal fold.

## Table of Species.

Uniformly brown.................................................................................exesorius.
Uniformly black................................................................................. obsidianator-
Trogus exesorius Brullé. Pl. 88, fig. 3.
Entirely fulvo-ferruginous, legs paler, tibiae and tarsi golden yellow; antenuae sometimes clusky or black above; wings uniformly fuliginous, with a stroug aeueous or violaceous reflection. Length, $\delta$ ㅇ, 17 to 20 mm . (After Cresson.)

This is the most abundant of the butterfly parasites which have been sent me. It seems to be almost exelusively a parasite of the different species of swallow-tails. Dr. Paekard says concerning its hosts and localitics: "Bred from pupa of Papilio asterias [polyxenes] by Dr. Harris, E. Norton, E. T. Cresson, etc., appearing at Cambridge, June 20th; also from P. troilus [Euph. troilus] (Mark) and P. turnus [Jas. glaucus] (P. S. Sprague) ; also from P. ajax and P. marcellus [Iphiclides ajax] West Virginia (Norton)." Professor Riley reared it in Missouri from Iphiclidea ajax, Papilio polyxenes, Euphoeades troilus and Jasoniades glaucus. Mr. Mundt has reared it in Illinois from the first and last of these. Mr. Lyman has reared it at Portland, Me., from polyxenes, Professor Cook in Michigan from troilus, and Mr. W. H. Edwards in West Virginia from ajax. The
only exception to its parasitism upon swallow-tails is sent me by Mr. Mundt who reared it from Vanessa eardui. Mr. Cresson records the species as eaptured in Canada, New York, Pennsylvania, Delaware, Georgia and Illinois, and hazards the opinion that it will probably prove to be a synonym of Ichneumon pennator Fabricus.

## Trogus obsidianator Brullé.

Deep black, immaculate; antennae orange-yellow; wings uniformly blackish fuliginous, with a strong aeneous reflection; first abdominal segment bicariuste, the carinae becoming obsolete before reaching the tip. Length, ס 우, 20 to 22.5 mm . (After Cresson.)

This insect has been reared from the chrysalis of Papilio polyxenes by Professor Riley. Mr. Cresson records the species from Pennsylvania, Illinois, Georgia and Texas.

## Genus HEMITELES Gravenhorst.

Metathorax with parapsidal grooves. Areolet of the fore wings pentangular in position, but incomplete, the outer nervure hyaline or wanting. Legs and antenuae generally slender. Spiracles of first abdominal segment more approximate to each other than to the aper of the segment; gastrocoeli at base of second abdominal segment wanting ; ovipostor distinctly exserted, short.

The species of this genus are as a rule parasites of parasites or, as they are ealled, "hyperparasites" or "secondary parasites." There is no wellproven exception to this rule on record so far as I know.

## Table of Species.

Thorax marked with red; wings banded with brown. ...utilis.

## Hemiteles utilis Norton. Pl. 88, fig. 4.

Female.-Black; antennae, anterior portion of prothorax, shoulders and a spot at sides of mesothorax, the legs, including coxae and trochanters, red; middle of posterior femora and extremity of tiblae brownish. Wings hyaline, nervures brown, white at base; tegulae white; stigma brown, without a white spot at base; a large brown band extends from the base of the stigma across the wing; areolet surrounded with white nervures, the exterior nervure wanting. Abdomen oral from the second segment, black, polished, shining ; joints 1 and 2 reddish at base and tip, the others margined with reddish posteriorly. Ovipositor a little longer than half the body, almost entirely reddish. Length, 3.75 mm .

This species is introduced into this paper for the reason that I find in the notes sent me by Mr. A. H. Mundt the statement that from an orer-wintered pupa of Heraclides eresphontes he bred a parasite which was determined for him by Mr. Cresson as H. utilis.

It seems likely that there remains some yet undiseovered primary parasite of erespontes from which this secondary parasite came.

## Hemiteles lycaenae sp. nov.

Female.-Shining black. Mandibles and palpi bright lemon-yellow; auteunae dullpiceous, honey-yellow at base; all legs, including coxae, honey-yellow; tegulae yellow aud venter of second abdominal segment boney-yellow. Wings hyaline, with no infuscated band ; nervures brown except at base, cubital nervure whitish, beyond incomplete; areolet, and subdiscoidal nervure also white beyond juncture with second recurrent nervure. IIead, thorax and abdomen very delicately shagreened; surface of mesonotum with reticulate carinae; anterior and posterior border of dorsnm of each abdominal segment perfectly smootl. Ovipositor sheaths one-fourth as long as abdomen. Length, 4.5 mm . ; expanse, 7 mm .

Described from one female specimen received from Mr. W. H. Edwards who reared it from the larva of Cyaniris pseudargiolus. In this case also there is probably a primary parasite of which we have no knowledge.

## Genus CRYPTUS Fabricius.

Female with joints of antenuae thickened in a nodose manner at their tip; antennae elongate, filiform, third joint usually three or more times longer than thick (if shorter then the metathorax is not arenlated), never thickened or expanded towards the middle. Areolet of fore wings completely enclosed, pentangular. Legs generally slender. Apex of first abdominal segment not much broader than the petiole, and but slightly bent; ovipositor distinctly exsertect.

I have not been able to determine the butterfly parasite of this genus specifically as I know of it only through a note of Professor Riley's to the effect that he has bred a species of Cryptus from Euphoeades troilus. The specimen cannot be found.

## Genus OPHION Fabricius.

Face pubescent; clypeus truncate at apex; ocelli large, prominent. Thorax and legs glabrous; metathorax rounded behind, not rngose; intermediate tibiae with two apical spurs; wings hyaline, stigma distinct, well developed, areolet wanting, cubitodiscoidal cell receiving both recurrent nervures. Abdomen petiolate, compressed; ovipositor short.

## Ophion bilineatus Say. Pl. 88, fig. 8.

## Ophion tityri Pack.

Honey-yellow; head yellow; antennae honey-yellow; mandibles blackish at tip; thorax with two somewhat reddish brown, longitudinal lines, almost obsolete; wings with fuscous nervures; costal nervure and stigma honey-yellow; tegulae paler than thorax; second segment of ahdomen hardly as long as first, and longer than second. Length, 8.75 mm . (After Say.)

Packarl's type of O. tityri was a male specimen reared from Epargyreus tityrus June 26, 1848, and is from the old Harris collection. As soon as it came into my possession I forwarded it to Mr. Cresson who informed me that he saw no reason for considering it as more than a variety of O . bilineatus of Say. The brownish stripes on the thorax seem, however, to be entirely lacking and the mandibles are lighter in color.

## Genus EXOCHILUMI Wesmael.

#### Abstract

Apical margin of clypeus truncate. Spiracles of metathoras oral. Cubito-discoidal cell receiving but one recurrent uervie; marginal cell lanceolate; median and submedian cells not confluent, third discoidal present, not narrowed at base; cubito-discoidal cell receiviug recurrent uervire in middle. Posterior femora marmed; tarsal claws not pectinate; posterior tarsi with first joint about twice as long as secoud. Abdomen petiolate.

## Exochilum mundum (Say).

Mate.-Body black ; head with the frout, uasus and auterior orbits greenish-yellow; antenuae fulvons sellow; three or four basal joints above black; the first joint beneath greeuish yellow; trunk with rather dense, short hairs; wings purple black; abdiomen much compressed; basal joint cylindrical; second segment as loug as the first or a little longer, compressed towards the tip; anterior pair of feet yellowish before; intermediate pair with a line before and base of tibiae yellowish; posterior pair with the tibiae, excepting the tip, and the tarsi, excepting the terminal joint, fulvous-yellow. Length, $20-25 \mathrm{~mm}$. (After Say.)

Mr. Mundt has bred this species from Vanessa cardui and Iphiclides ajax. The single specimen which he sent on and from which the species has been determined agrees with this deseription except that the posterior tibiae are black and the tarsi are dark gray.

## Genus ANOMALON Gravenhorst.

Head buccate, or subbuccate; front with the median projection uear the base of the antennae present or wauting, face more or less uarrow. Clypens indistinctly distinguishable, apex acutely augulate or apicniate. Antennac longer than the boils, equal to it in length, or shorter. Metathorax punctate, often longitudinally sulcate (broadly, but not deeply). Abdomen compressed, joiut 1 sublinear; terebra shortly exserted, valves towards apex usually dilated; legs slender, or the posterior are rather strong; posterior tarsi cither incrassate or simple, linear, first joint about twice as long as second. (After IIolmgren.)

The cubito-discoidal cell receives but one recurrent nervure, and this before the middle ; the marginal cell is lanceolate; the third discoidal cell is present and is narrowed at base.

## Anomalon pseudargioli sp. nov.

Femate-General color black and rufous. Face yellow, cheeks behiud eyes rufons, yertex and occiput black with the usual yellow spots each side of ocelli; antennal scape sellow below, black above, pedicel and joint 1 of funicle black, rest of funicle rufous. Thorax black above and below, the outlines of the mesoscutum defiued by an irregular, rufous band, which fails before and behind ; mesoscutellum with its anterior half rufous; metanotum with a rufous band each side; front and middle legs yellow, hind cosae, femora and tibiae black with a rufous spot on cosae, and the femora with a varying amount of same color; wiugs perfectly hyaline, reins dark brown. First and second abdominal joints black, slightly rufous belorr; remainiug joints rufous, with a dark shade along dorsal line, extending down more on the sides of joints 5 and $f$, thau ou 3 and 4. Length, 13 mm .; expause, 18 mm .

Described from four female specimens. Three were sent me lyy Mr. W. H. Edwards, who reared them in July from pupae of Cyaniris pseudar-
giolus, and one was sent by Mr. Scudder, who reared it from the chrysalis of Uranotes melinus.

## Genus MESOCHORUS Gravenhorst.

Head transverse, short, not buccate. Clypeus not distinguishable. Eyes oblongorate. Antennae about as long as body, setose. Metathorax with a straight, superior area. Abdomeu oblong-fusiform; first segment slightly curved, spiracles almost in the middle; last ventral segment with the female rather large; anal stylets of the male rather long, filiform; terebra of the female exserted for a short distance. Wings with a rather large rhomboidal, areolet. Legs moderate or slender. (After Holmgren.)

The species of Mesochorns are without doubt often hyperparasites; whether always so we cannot say with certainty.

Table of Species.

Thorax entirely black............................................................................ pieridicolus. Thorax entirely sellow, or marked with yellow-brown . .scitulus.

## Mesochorus pieridicolus (Packard).

## Campoplex pieridicola Packard.

Female.-Black: head black on the vertex and occiput; orbits and front below the antemae bright yellow; a slight reddish tinge in the middle. Palpi pale honey-yellow. Antenuae brown, pale yellowish at base, second joint pale brown above, third yellow, fourth and fifth pale yellowish brown, and thorax shining black, with fine, white, appressed hairs. Metanotum full, rounded, smooth, and polished, with a narrow mesial ridge. Tegrulae and base of wings pale greenish-yellow. Wings clear; stigna pale brown; veins concolorous; areolet rather large, rhomboidal. Legs, including the cosae, honey-yellow; tarsi of fore and middle legs dusky towards the claws, those of the hind legs a little dusky, except on basal two-thirds of first joint, and growing clarker toward the claws. Ablomen long and narrow, compressed towards the end, with a minute, slender ovipositor, not quite so long as the abdomen is wide, shining black with a yellowish band in the middle, the posterior edge of the second and anterior two-thirds of the third segment being yellow. There is a yellow dot at the end of the pedicel, being an cxtension of the pale yellow under surface of the three basal segments; end of abdomen obliquely truncated. Length, 4 mm . (After Packard.)

Dr. Packard described this species from a single specimen, and I have seen only his type. The specimen is labelled: "From Pieris rapae," and this is all the information which we lave concerning it. It may or may not be a secondary parasite.

## Mesochorus scitulus Cresson.

Male, Femate.-Pale honey-ycllow or luteous; head broad; spot covering ocelli, and tips of mandibles black; occiput of 9 more or less fuscons; antennae long and slender, pale testacenns, sometimes slightly dusky, scape paler; mesothorax fuscous in 9, honey-yellow with dusky sides in $\delta$; scutellum and region honey-yellow; disk of metathorax more or less blackish or fuscous; tegulae pale luteous; wings hyaline, irridescent, nervures and stigma lnteous; legs pale luteous, apex of posterior tibiae and tips of tarsal joints dusky; abdomen fusiform, very slender at base, black above, with a large, discal, pale luteous spot covering apical half or two-tbirds of second
and basal half, or two-thirds of third segments; venter pale luteous; ovipositor of $f$ longer than basal segment. Length, $\mathbf{1 . 5} \mathrm{mm}$. (After Cresson.)

This species was bred by Mr. Cresson (twenty-four specimens, together with four specimens of a Pezomachus) from a bunch of bright yellow cocoons (probably those of a Microgaster) found attached to a blade of grass in Pennsylvania.

I have scen three specimens of what seems to me to be this species in the National Mnseum collection at Washington which were received from Miss M. E. Murtfeldt of Kirkwood, Mo., Oct. 18, 1881 and by her said to be parasitic on some "large parasite" of Eurymus philodice.

## Genus LIMNERIA Holmgren.

Head moderately large, transverse, not inflated; eyes naked, notemarginate; clypeus normal, not carinate or denticulate. Thorax longer than high; metathorax distinctly areolated, not produced at apex. Stigma of fore wings of moderate size; areoletsmail, usually triangular, often petiolate, sometimes absent. Abdomen moderately broad and moderately or slightly compressed towards apex, the incisures between segments very distinct; petiole slender, longer than the transverse post-petiole.

Table of Species.

Abdomen almost entirely rufous.............................................................. ${ }^{\text {. }}$.

## Limneria fugitiva Say.

Body black; antennae in both sexes black; mandibles and palpi white; tegulae white; wings hyaline, nervures black, whitish at base, areolet very small, petiolated from the radial cellule; metanotum not excarated behind, but with "somewhat raised lines"; abdomen arcuated, towards tip rather abruptly clavate; punctures very small; ovipositor as long as tip of abdomen; feet honey-yellow with a white reflection; posterior tibiae white with a black tip and base; posterior tarsi black, base of first joint white; in the male the white of the posterior tibiae is less obvious. Length, from 6 to 7.5 mm . (After Say.)

Say reared this species in Indiana from a "pretty white cylindric cocoon with maculated luack bands."

As a butterfly parasite this species has been reared from Pholisora catullus by Professor Riley in Missouri, from Chlorippe celtis by Mr. W. H. Edwards in West Virginia, and from Clilorippe clyton by Mr. A. H. Mundt in Illinois.

Limneria limenitidis sp. nov. Pl. 88, fig. 5.

#### Abstract

Male.-General color black. Palpi whitish; lower face with dense white pile; scape of antennae reddish below, blackish above. flagellum black; top of head and dorsum of thorax with sparse, fine white pile; tegulae dirty white, wings hyaline, nervures brown, costa black; all cosac black; front legs entirely light honey-yellow; trochanters, femora and tibiac of middle legs dark reddish jellow, tarsi much lighter and with each joint slightly dusky towards tip; first joint of hind trochanters black, second joint yellow; hind femora very dark rufous, lighter on the inner side; hind tibiae nearly black, spurs yellowisb white; hind tarsi uniform in color with their tibiae, a very narrow band of white at base of first joint only. Abdomen rufous, except

joint 1, first four-fifths of joint 2, and first one-fourth of joint 3, its entire surface covered with very short pile. Punctation of head and mesonotum itentical, fine and close; metanotum with a more rugose punctation, and with a faint median, longitudinal channel ; two diverging earinae arise each side of this median channel, at front of metanotum, and meet two converging carinae at half the length of this sclerite. Length, 8 mm ; expanse, 12 mm .

Described from two male specimens, both reared from Basilarehia archippus, by Mr. W. H. Edwards, at Coalburgh, W. Va. One is labelled Jnly 15, 1886, and of the other Mr. Edwards writes that it left the archippus larva at the latter's second moult. The cocoons of both individuals were also sent by Mr. Edwards. They are 6 mm . long and 2.5 mm . broad, of a regular oval shape and spun of grayish white silk; near either end is an irregnlar, interrupted black band, and upon each end are three or more black spots.

## Genus PIMPLA Fabricius.

Ilead transwerse, short, cheeks not swollen; elypeus distinet, depressed or subexcavated at apex; antennae porrect, filiform, scape excised at apex; eyes oblong, emarginate near base of antennae. Thorax robust, moderately elevated; scutellum with an obtusely rounded apex; metanotum low, spiracles oval or circular; tarsal claws simple, sometimes lobed at base with female; areolet of fore wings always complete, triangular. Abdomen sessile; in females of most species oblong or oblong-ovate, in males narrower, subcylindrical or sublinear; narrower than the thorax or very slightly broader, strongly, or faintly and thiekly punctate; joints 2 to 7 usually transverse, sometimes subquadrate with the males, the ventral borter of the two last with the females longitndinally fissured; joint l subquadrate, or scarcely longer than broad, rarely slightly shorter, nsually with a longitudinal carina. Terebra usnally shorter than abdomen, but may equal it in length or exceed it.

Pimpla annulipes Brullé. Pl. 88, fig. 6.
Male, female-The head is sparsely and finely punctate, especially on the face, which is sometimes so pubescent as to appear opaque, and sometimes has the pubescence mostly removed so as to appear subpolished. A minute, glabrons tubercle on the disk of the face. The palpi are generally dull, dark rufons in ". \%, sometimes pate rufous, sometimes almost whitish, but in the $\delta$ they are always whitish; the anteunae are about four-fifths as long as the body; the lst joint of flagellum in $\delta, 3-3 \frac{1}{2}$ times, in 9 , $4-5$ times as long as wide, the entire flagellum, $\delta$ of, tinged with rufous beneath. The thorax is finely and sparsely punctate above and below, and the metathorax is contluently and rather coarsely punctate, and usnally more or less covered with fine, whitish pubescence so as to be opaque; the posterior declivity and a small area behind the scutel glabrous and polished, the two glabrous areas never quite confluent. Carinae all obsolete, except a small basal portion of the two central ones. The abdomen is confluently punctate and opaque; the usual tubercles are subobsolete, and the sides and extreme tips of the intermediate joints are often more or less tinged with sanguineous in $\circ$, sometimes conspicnously so, but never in $\delta$. In joint 1 the nsual carinae scarcely extend halfway to the tip, and enclose between them a glabrous, circular, subbasal excavation. The ovipositor is half as long as body; the sheaths pubescent, scarcely tapered, and basally rather narrower than the last tarsal joint of the hind legs. Venter dull rufous, blackish at tip, sometimes all blackish, execpt extreme basc. The legs are pale bright rufons, but in the front legs of more than one-fourth of the $\delta \delta$ the trochanters are whitish; in the middle legs $\delta$ 倝, the second fourth of the tibiae is whitish, and very rarely the first fourth and the terminal half blackish exteriorly ; and
in the hind legs the of extreme tips of the femora and the whole tibia except the second fourth are black, and the tarsi are pale dnsky, often with the base of cach joint gradually a little paler. The areolet of the fore wings is mostly rhomboidal, very rarely subtruacate anteriorly, but never peduncled. Length, $\delta, 3.5-11 \mathrm{~mm} ; ~ ;, 5-12 \mathrm{~mm}$. (After Walsh.)

This is a well-known parasite of many lepidopterous larvae. It has been reared from Carpocapsa pomonella, Acrobasis juglandis, Aletia xylina, Grapholitha olivaceana, Coleophora cincrella, Orgyia leucostigma, and other unreared larvae. As a butterfly parasite it has been reared but once, viz. : by Mr. J. B. Sinith, from a chrysalis of Iphiclides ajax at New York. It is also probably a parasite of Chlorippe clyton. Professor Riley has a pupa of this butterfly which has been broken open, revealing a large ichneumonid pupa which seems to be that of a female Pimpla annulipes.

## Genns GLYPTA Gravenhorst.

Head transverse, short, cheeks not swollen, entire; clypeus slightly convex, apex round or subtruncate; antenuae filiform; eyes nearly entire. Thorax robust; scutellum rounded at tip ; metathoracic spiracles minute, subcircular; legs usually slender, tarsal claws with distinct pectinations, rarely simple or setose internally; wings generally with no areolct, rarely with a complete onc. Abdomen snblanceolate or linear, rarely ovate-elongate; joint 1 with a clelicate, distinct carina; joints 2 to 4 with two oblique linear depressions; terebra of female at least as long as abdomeu and lssuing from apex; genital valvules of male nsually incrassate, with obtuse apex, rarely narrower with acuminate apex.

## Glypta erratica Cresson. Pl. 88, fig. 7.

Female.-Black, shining; clypens, mandibles, except tips, palpi, tegulae and line before, whitish; antennae brown-black, darker at base, apex and above; wings hyaline; legs, including coxae, yellowish-red; trochanters whitish beneath, posterior pair blackish above; intermediate tarsi fuscous, pale at base of joints; base and apex of posterior femora blackish; their tibiae black, with a white stripe above, not reaching the apex and interrupted by a black spot near base, the tarsi black, more or less white at base of joints; face with a median rounded swelling. Thorax minutely and closely punctured; metathorax rounded, smooth, shining, obsoletely punctured, apex enclosed by a well-defined arcuate carina; abdomen finely and densely punctured, the oblique lines deeply impressed, first segment with two sharply defined, longitudinal carinae at base, becoming obsolete on micldle; venter piceous, ovipositor as long as abdomen. Length, 9 mm .

Male.-More slender than $\%$; the metathorax above has two, more or less distinct, oblique carinae, and the anterior coxae are whitish. Length, 8 mm . (After Cresson.)

This parasite, which is said by Cresson to be a common species in New York, Delaware, Pennsylvania and West Virginia, was reared by Professor Riley in Missouri from a chrysalis of Polygonia comma.

## FAMILY BRACONIDAE HALIDAY.

## Genus MICRODUS Nees.

Maxillary palpi ojointed, labial 3 -or 4 -jointed. Face not produced or rostriform. Mesothorax distinctly trilobate. Mesopleura with a rugulose furrow. Three cubital areolets, the first confused with the praediscoidal (after Marshall).

# Microdus sanctus (Say). Pl. 88, fig. 10. 

Bussus sanctus Say.
Body hlack; palpi tinged with piceons; thorax, pleura, pectus and the two auterior pairs of feet immaculate; wings blackish violaceous, with a hyaline literation iu the middle; nervures black; separating nervure between the first cubital and the first discoidal cellules widely interrupted; second cellule triangular; cubital cellule rather large; metathorax and abdomen bright sanguineous, posterior coxae and thighs bright sanguincous, the intervening trochanter black; posterior tibiae dull sanguineous, their tips dusky, their tarsi blackish; ovipositor nearly as long as body, ferruginous with black valvules. Length, 7.5 mm . (After Say.)

Of this species I have seen two female specimens, one from Pholisora catullus, reared by Miss Murtfeldt at Kirkwood, Mo., (no date), and the other from Thanaos juvenalis, reared by Mr. Scudder, October, 1887, at Cambridge.

Note.-The remaining Braconidae, parasitic upou butterflies, beloug to the subfamily Microgasterinae aud have been treated at my request by Dr. Riley, and from this fact have been removed from this, their uatural place, to the eud of the chapter.

## FAMILY CHALCIDIDAE WALKER.

## Genus CHALCIS Fabricius.

#### Abstract

Antennae 13-jointed, short and stout, pubescent, inserted in the middle of the face, scape moderate, third joint minute; scutellum slightly bidentate; abdomen subpetiolated, pointed in the female, but not much produced, first segment about half its entire length; hind femora armed with large teeth. (After W. F. Kirby.)

Table of Species.
Hlud femora black on the outer side flavipes. Hind femora yellow on the outer side, with black marking robusta.

$$
\text { Chalcis flavipes Fabricius. Pl. } 88, \text { figs. } 14,15 .
$$

## Chalcis ovata Say.

IIead black, with golden sericeous hair which is indistinct on the vertex; antennae testaceons bencath towards tip; thorax with dilated dense punctures, a little sericeous with golden hair; tegulae yellow; wings hyaline; nervures fuscous, at base yellowish; fect bright yellow; basal half of anterior pairs of thighs black; posterior thighs black with a yellow spot on the tip above, dentate along posterior edge; posterior tibiae piceous on basal incisure ; terminal spine rohust, shorter than the first tarsal joint; abdomen subovate, polished; first segment nearly glabrous, second segment hairy on each side; remaining segments hairy near their tips. Length, 5 mm . (After Say.)

I have previously reeorded this parasite from Chlorippe elyton (See Bull. 5, Div. Ent., U. S. Dept. Agr., p. 8). It was reared by Professor Riley from pupae of Agraulis vanillae in Missouri, and it has also been sent me by Judge W. B. Thomas who reared it at Athens, Ga., from the same species. It was also reared from Chlorippe clyton by Professor Riley in Missouri.

## Chalcis robusta Cresson.

Black, clothed with a short, golden-yellow pubescence; head broader than the prothorax, the face, checks and occiput densely elothed with golden pubescence. Thorax closely and rather deeply punctured, opaque; scutellum somewhat produced behind, carinate at tip which is densely clothed with golden pubescence, as well as the extreme sides near the base; metathorax roughly rugose; tegulae bright rellow. Wings faintly tinged with pale fuscons. Legs, excepting the cosae, bright yellow; posterior coxae robust, polished; their femora much swollen, black within except near the tip, above and on the outside a large, oblique, black spot not reaching the upper margiu, but confluent beneath with the black of the inside; in one specimen this spot is entire and not confluent beneath with the black of the inside, and the apical third within is yellow; lower margin armed with a row of nine or ten small, obtuse black teeth and a large obtuse one near the base; their tibiae curved, acnte at tips; tarsi black at tips. Abdomen subsessile, robust, convex, orate, sometimes faintly compressed and pointed at tip, smooth and polished, and the posterior margins of the apical segments more or less fringed with yellowish pubescence. Length, 6 mm . to 8 mm . ; expanse of wings, 10-12 um. (After Cresson.)

This large and handsome chalcid has been reared by Mr. H. G. Hubbard at Crescent City, Fla., from the chrysalis of Heraclides cresphontes, from whieh it issued through a large hole in the thorax. It was originally described by Mr. Cresson from Cuba.

## Genus ENCYRTUS Dalman.

Female.-Anteunae 11-jointed, inserted not far from the border of the mouth, moderately thick, and, with the exception of the scape, very seldom compressed; the scape is often strongly broadened; the elub is rounded, or with a slight oblique truncation at tip. The facial impression is rather large and often quite deep. The mesonotum is transversely arched, shagreened, and more or less lustrous; the scutellum shows a different sculpture. The wings are always developed and ciliated; the marginal vein is present, seldom very short; the stigmal is moderately long. The ovipositor is not so long as half the abdomen.

Mate.-The flagellar joints are slightly or not at all compressed, aud covered equally (not in half whorls) with hairs.

## Encyrtus montinus Packard. Pl. 89, fig. 4.

Female.-Scape of antennae somewlat broadened below near tip; pedicel cylindrical, twice as long as broad; first funicle joint longer than broad; succeeding joints increasing very slightly in width but not increasing in length; club nearly as long as preceding three funicle joints together, ovate, but little broader than sixth funicle joint. Fore wings cloudy, with a single, broad, clear band extending across the wing from just beyond the stigma to posterior border, curving slightly outwards; an oblique, hairless line also extends from the stigma across towards base of wing, and the course of one of the spurious veins is seen extending from the hairless line to the hyaline baud. The mesonotum is very finely shagreened and is also corered with sparse, large punctures. The general color above is light metallic green; the head, pronotum, tegulae and tip of abdomen dull yellow; the whole body below and at sides dull yellow or testaceous; legs yellow, the hind thighs somewhat dusky above; antennal scape testaceous, pedicel and first four funicle joints yellowish brown with dark hairs, funicle joints five and six white with white hairs, club black with black hairs. Length, 2 min ; expanse, 4 mm .

This description is drawn up from Mr. Sanborn's original specimen, which is a female, however, and not a male as Dr. Packard supposed, and from a captured female received from Mr. Scudder.

This species is a true Encyrtus and belongs to the chalcostomus group, approaching very closely to E. lunatus Dalm. It has no connection with E. swederi with which Dr. Packard compares it and which belongs to Comys Foerster. All of the chalcostomns group, including lunatus, are parasites of Coccidae, the only possible exceptions being barbarus and rogenhoferi, the habits of which are not known. Moreover, all are parasites of the gemus Lecanium. All that we know of E. montinus is that it was "found alive in an old chrysalis casc" of Oeneis semidea by Mr. Sanborn in the White Mountains, and there is nothing is this information to contradict the hypothesis that this specimen came from a Lecanimm, perhaps on the same plant, and that its presence in the old chrysalis was purcly accidental. It may be stated in further support of this view that no true Encyrtus is known in Europe to have been bred from a lepidopteron, and no specics of the whole snbfamily Encyrtinae from any Diurnal. Encyrtus bucculatricis Howard is the only American exception to the former rule. It is very probable, therefore, that E. montinus is not a butterfly parasite and I introduce the redescription for the reason only that it has been so considered by others. There is, however, still a bare possibility that it may yet turn out to be a parasite of the White Mountain species.

## Genus COPIDOSOMA Ratzeburg.

Female.-The antennae arise near the border of the mouth; the scape is long and slender; the six-juinted funicle long and slender, or short and comparatively thicker; the club is either long, delicately bent and somewhat rounded at tip, or it is thicker and markedly obliquely truncate. This truncation is produced by the drying of a strip of more delicate membrane upon oue side of the club. Front and vertex closely punctured, without larger deep punctures. The mesoscutum and often the scutellum have with most species a sculpture which was called by Ratzeburg "schuppig" (scaley), and also a thicker punctuation with round or aciculate puuctures. The marginal vein is either lacking, or it is a little shorter than the stigmal. The wings are hyaline. The ovipositor is very long, but may also be entirely hidden.

Mule.-The male resembles the female in the form of the body, in the punctuation, and also in the relative proportion of the wing veius, differing to a marked degree only in the antennac. These are given off near the border of the mouth as with the female; the scape is long and slender, the pedicle shorter than the first funicle joint; the funicle is rather thickly covered with short hairs (the hairs shorter than the joints), with the joints separated above more than below; the club is about as thick as the funicle. The base of the scutellum has a more or less delicate longitudinal carina, but no furrow.

Copidosoma turni (Packard). Pl. 89, fig. 5.

## Encyrtus turni Packard.

Female.-Antennae short and curved; club large and strongly truncate obliquely from tip nearly to base; first funicle joint much shorter than pedicel and as thick as long; succeeding funicle joints widen to joint 6 , which is cousiderably wider than long. Punctation of face very delicate; mesoscutum delicately shagreened; mesoscutellum with a delicate scaly sculpture. Marginal vein of fore wings slightly shorter than the stigmal. Color: Head and mesoscutum bright metallic green or blue, somtimes head appearing blue and scatum green; pronotum and mesoscutellum copper-bronze; ab-
domen shining black with metallic green and blue reflections; antennae dark brown; all coxae dark with metallic reflections; all femora dark brown, the hind pair slightly metallic; all tibiac brownish for a little more than basal half, tip honey-yellow; all tarsi and tibial claws yellow. Length, 2 mm ; expanse, 3.9 mm .

Male.-Agrees with female in all characters mentioned except antennac. These arise in a deep groove half way between eyes and border of mouth. The scape is short, reaching ouly to middle of eyes; pedicel slightly shorter than first funicle joint; remaining funicle joints all subequal in length and width, with short hairs, and well separated from above; club cousists of two joints, similar to funicle joints, easily dis. tinguished, the last one rounded at tip. Color of the antennae, honey-yellow throughout.

The serics of specimens of this species studied consists of seven females and one male, all obtained by E. Norton from Jasoniades glaucus. Most of the species of Copidosoma which I have studied infest small lepidopterous larvae, which they inflate upon pupating, giving to the caterpillar skin a swollen appearance, frequently stretching it until the cells of the little parasite can plainly be seen. In the absence of any notes concerning Mr. Norton's experience, I imagine that his specimens were reared from a glancus larva which was not more than half grown.

## Genus PTEROMALUS Swederus.

Mandibles 4 -lentate, the left rarely 3 -dentate; cheeks often compressed; clypeus emarginate in middle; eyes sometimes hairy; antennae usually inserted slightly below middle of face upon a convex, slightly protruding portion; scape not short, ringjoints distinct, club not stylate. Thorax compact, not elongate; metanotum usually punctulate, spiracles rarely large. Wings with the stigmal rein usually shorter than the postmarginal, or equal to it in length; marginal not thickened; usually (always in male) immaculate. Abdomen often rotund; venter in male rarely with a straight fold. Posterior cosae broadly ovate, not pubescent at posterior base. (After Thomson.)

Table of Species.

| Clypeus 2-dentate in middle........ <br> Clypeus not 2-dentate. <br> Femora of female honey-yellow |
| :---: |
|  |  |
|  |  |

## Pteromalus chionobae sp. nov.

Femelle.-Clypers 2-dentate in middle at apex; antennae inserted somewhat below middle of face, scape reaches to anterior ocellus; flagellum well clothed with short white pile; facial impression well-marked; eyes smooth; metanotum with a strong and complete median carina, spiracles small, spiracular sulcus plain, but not reaching to acetabulum, neck punctate, border of acetabulum smooth, with a row of deep shallow punctures just above it. Postmarginal vein equal to stigmal in length, speculum small. Head and thorax densely puntulate; abdomen smooth, ovate, concare abore. Color bronzy green; scape honer-yellow; pedicel below honey-yellow; femora bromin, tibiae and tarsi lighter towards tip. Leugth, 3 mm . ; cxpanse, 5.5 mm .

Two female specimens of this species were reared by Mr. Scudder in August, 1887, from a chrysalis of Oeneis semidea. The chrysalis was carefully dissected, but no more parasites could be found.

## Pteromalus puparum Linnaeus. Pl. 89, figs. 1, 2.

Female.-Head a little broader than the ablomen, subtransverse, greenish bronze, closely punctate, slightly narrowing behind the eyes, vertex emarginate in middle; ocelli quite large, placed in a triangle; face quite flat, antennal grooves scarcely showing, cheeks quite long, convex, slightly compressed; eyes subovate, subconvex; clypens emarginate at apex in the milde; mandibles armed with four achte teeth, apical one externally sinuate; antemae long, filiform, inserted in the middle of the face, bases close together, brown or fuscons, scape linear, yellow, joint 2 oblong, 3 small but distinct, $t$ a little larger than $3,5-10$ equal in width but growing slightly shorter, club conico-elongate. Thorax moderately robust, above slightly convex, almost smooth, very closely squamoso-punctate; metanotum quite loug, very punctate, nucha almost globose, uo median cariua, but strong, arcuate, lateral folds, spiracles not small, suboval, sitnate in the spiracular sulcus just beliud the suture. Wings lyaline, subcostal cell broad, margiual rein delicate, longer than stigmal and a little shorter than postmarginal. Abdomen ovate, flat above, below stightly convex, sides rounded, a little shorter than thorax, considerably broader, joint 1 dark blue, not transverse but hidden in uncha. Coxae green, femora fuscons bronze, tibiae occasionally concolorous. Mesopleura delicately punctate.
Macte.-Difters from femate in its thinner more strongly pilose antenuae, oblong abdomen, anteus above, head broader than thoras, green, femora and tibiae always yellowLength, 3 to $\pm \mathrm{mm}$. (After Thomson.)

This insect is common to Europe and North America, and is the commonest parasite of Pieris rapae. It has also been reared from Enrymus philodice by Mr. Lyman, from Eurema lisa by Mr. Mundt, from Agranlis vanillae by Professor Riley, from Polygonia satyrus by Mr. W. H. Edwards, from Euvanessa antiopa by Mr. Ashmead, from Vanessa atalanta by Mr. Lyman, from V. cardui by Mr. Scudder, from Basilarchia archippus by Mr. Scudder, and has been caught ovipositing upon an Epargyreus tityrus larva by Professor Riley.

Pteromalus vanessae Harris. Pl. 89, fig. 3.
Dr. Harris' types of this species, I am informed by Mr. Henshaw, are not contained in the IAarris collections at the Boston Society of Natural History, and as I know of no anthentic description of the species, I am obliged to take it for granted, as Dr. Packard evidently did, that the Pteromalus commonly reared from Euvanessa antiopa and Polygonia interrogationis at the north is the one to which Harris gave this name.

I am unable, after close examination of the specimens reared from these butterflies, to satisfactorily distinguish them structurally from puparum, and am reluctantly compelled to consider for the present that vanessac is but a variety of puparum. The specimens in my possession reared from antiopa and interrogationis are at least a fourth larger than the largest females reared from Picris rapae, and will average darker in color. I have no males reared from either of these butterflies, but males of the large form reared from Heraclides cresphontes resemble in all respects males reared from rapac.

Specimens of this form have been reared as follows: from Heraclides cresphontes by W. H. Edwards, A. H. Mundt and Professor Riley; from Euphocades palamedes by Professor Riley ; from Ascia monuste by Professor Riley ; from Polygonia comma by myself; from Evanessa antiopa by many observers; from Polygonia interrogationis by many observers.

Pteromalus archippisp. nov. Pl. 89, fig 3.

Femate.-Resembles in size and coloration $P$. puparum var. vanessac, except that all femora are honey-yellow, instead of dark brown or metallic. The punctation of the notum is deeper and closer and is identical on all segments. The nucha of the metanotum is scarcely clevated and is not at all globose; the median carina is faintly indicated, and the spiracular sulci are very decp, much curved and reach about half way to the acetabulum.

Described from three female speeimens sent by Prof. A. J. Cook to Professor Riley, and reared September 13, 1857, from a clirysalis of Anosia plexippus. A note concerning the rearing has been published by Mr. C. P. Gillette in the Canadian Entomologist for July, 1888 (p. 133), in which he states that over fifty specimens of the parasite issued on the above date from a single chrysalis of plexippus.

## Genus DEROSTENUS Westwood.

Face usually sunken aftcr death; vertex rarely acute, smooth; eyes large, usually hairy, usually emarginate interiorly; antenual grooves often furcate, sending a branch to the inuer side of each prbit. Auteanae iuserted below middle of face; scape wholly or partly pale; ring joint usually distinct; funiele 3 -jointed; club rarely two-jointed with both sexes. Pronotum plain, anterior margin acnte ; parapsidal sutures indistinct; sculpture faint, rarely subsquamons; metanotum often carinate. Wings ample, subcunciform; costa longer than marginal; stigmal short, postmarginal usually longer, but rarely absent.

```
Derostenus antiopae (Packard). Pl. 89, fig. 7.
```

Entedon antiopae Packard.
Male.-Postmarginal vein distinct. Scutellum with no median groove. Abdomen rotund, with a very short petiole. Scape of autemae long, cylindrical; flagellun with short hairs. Eyes slightly emarginate, not hairy. General color shining black; antennae with brown club and fnnicle, scape, pedicel and ring-joint yellow; all legs jellow (cosae cannot be seen) ; metanotum and petiole yellow-brown. Length, 1.6 mm .

The only specimen of this parasite known is a male. It is in poor condition and very dusty, and is glued firmly to a large card. It is marked " 477 ," and is said to be from the old Harris collection. As its specific name indicates, it was reared from Euvanessa antiopa.

## Genus CIRROSPILUS Westwood.

Head transverse; rertex not broad; eyes sparsely puhescent; genal sulcus distinct; clypens not denticulate at apex ; antennae inserted far below middle of face, distant at base, funicle 2 -jointed, club 3 -jointed. Thorax sublepressed above, pronotum not
short but transverse; mesonotum deusely minutely puuctate, and with deep sulci, coutinuons with the lines of the scutellum; scutellum depressed, with dorsal lines slightly couverging towards apex; postscutellum large; metanotum not short, median carina distinct; costal cell of fore wings moderately broad, submarginal veiu with five to six bristles. Abdomen subsessile, ovate, depressed above, hardly couvex below. Mesopleura well separated, smooth. Posterior tibiae l-spurred, coxae grauulate exterually. Body usually metallic and with pale markings.

## Cirrospilus niger sp. nov.

Female.-Shiuiug black, with black bristles. Anteuane yellowish below; all legs, jucluding coxae, houey-yellow; abdomen yellowish below at base. Posterior border of pronotum perfectly smooth; anterior border of pronotum, all of mesoscutum and scutellnm finely shagreened; metanotum without sculpture, with a very fine median, longitudinal suture through its auterior portion, and a corresponding cariua through its posterior portion; spiracles of this segment perfectly round, prominent, lateral fringe of hairs white and strong. Abdomen lozenge-shape or nearly round, as broad as thorax, bnt much shorter. Length, 1.5 mm . ; expause, 3.25 mm . ; greatest width of fore wing, .58 mm .

Male.-Differs from female in following respects: Abdomeu loug oval, considerably narrower in frout, nearly as long as thorax and quite as wide, the first segmeut above bearing a large, light-brown, circular spot; all coxae shining black; hind femora black above, this color extending downwards at middle; front femora slightly dusky towards base above. Leugth, 1.6 mm .; expause, 3.25 mm .; greatest width of fore wing, 49 mm .

A large number of both sexes of this species were reared by Mr. Scudder from the "s tomb-stone" pupae of some unreared Eulophus, which had previously destroyed the half grown larva of Vanessa atalanta. It is, therefore, a hyperparasite.

## Genus TETRAS'TICHUS Haliday.

Head with a distinct geual sulcus; clypeus bidentate at middle of apex; ocelli usually placed in a curved liue; eyes smooth or rarely pilose, ovate or subrotuud; vertex narrow; impressed line before the ocelli usually distinct; anteuuae usually inserted a trifle below the middle of the face; scape very rarely reachiug above the ocelli; ring-joint very small but easily seen, rarely conforming with the joints of the funicle; funicle 3-jointed; club 3-jointed, the last joint smaller, often setigerous. Prouotum with the posterior border, especially on the sides, hairy. Mesoscutellum with four bristles behind the middle, usually with two parallel, longitudinal, deeply impressed lines. Metanotum usually short, rarely punctulate; apex in the middle not produced, but angularly emarginate; often carinate; fimbriate border with 1 to 4 bristles. Wings clear; costa longer than margiual ; no postmarginal ; stigmal quite long, club distiuct, uncus conspicuous; submarginal with 1 to 5 bristles. Abdomen ovate or couico-triangular; terebra rarely much exserted. Posterior tibiae l-spurred, tarsi shorter than tibiae with joints subequal in length. Male antennae rarely with erect hairs, usually with long appressed hairs; riug-joint always distinct, usually transverse (adapted from Thomson).

Table of Species.
Mesoscutum with au impressed, median, longitudinal line.
Antennae inserted just above clypens................................................................. Antennae inserted considerably above elypeus.

Wing veins pale...................................................................... saundersii.
Wing veins dark........................................................................... .

## Tetrastichus semideae (Packard).

Eulophus semideae Packard.
Male, female. - Antennae inserted slightly above clypeus. Mesoscntum with an impressed, median, longitudinal line. Mesocutellum with two parallel, impressed, longitudinal lines. Flagellum of male antennae with many long appressed hairs. Abdomen of female a little longer than thorax and about as broad, rounding out to joint 3 which is broadest, and thence, with straight sides, tapering to an acute point; the whole abdomen flattened and usually tilted upwards. Abdomen of male shorter and narrower than thorax, flattened and sub-oval. General color bluish green; antennae brown, darker in male than in female; all tibiae and tarsi honey-yellow; all coxae dark brown, yellowish at tips; front femora dark metallic except at tips; middle and hind femora dark brown except at tips. Length, 1.85 mm . ; expanse, 3 mm .

This species has been reared in eonsiderable number, from Oeneis semidea by Mr. Scudder who has sent me a goodly series.

## Tetrastichus saundersii (Packard).

## E'ulophus saundersii Packard.

Of this species of Dr. Packard's there remaiu but three greatly mutilated specimens $\cdot$ The antennae of all are gone and all are pinued with large pins through the thorax so as to destroy the characters. The species from the wings does not belong to the Enlophinae but to the Tetrastichinae, and may provisionally to be placed in Tetrastichus. There is no hope of a proper placing of this species until it is reared once more. The best we can do is to reproduce Dr. Packard's original description :

Three females. A minute species compared with semideae, but otherwise closely allied to it in structure and color; the abdomen, however, is considerably shorter and thicker, being scarcely longer than the thorax, while in semideae it is as long as head and thorax together. Antemnae of the same form as in semideae but much shorter, the joints between the second and the club being longer than broad, while in semideae hey are twice as long as thick; they are brown and hairy. Wings much as in semideae, but the veins are much paler, less distinct. Legs colored much as in semideae. Trochanters brown, femora brown, pale at base, and whitish at tip; tibiae and tarsi white, except tarsal joints which are pale brown. Abdomen, like the rest of the body, deep blue with a greenish tinge, much shorter than in semideae and conical ovate, the tip not being at all produced. The body is smooth with very fine hairs. Length, 1 mm .

These specimens were reared by.Mr. Saunders in Ontario from a chrysalis of a Thecla presumed to be edwardsii.

## Tetrastichus theclae (Packard). Pl. 89, fig. 6.

## Eulophus theelae Packard.

Male.-Antennae inserted considerably above clypens. Mesoscutum with median longitudinal sulcus. Mesocutellum with two distinct, parallel, longitudinal sulci. Submarginal vein with two bristles. Antennal scape not reaching to the eyes. Abdomen broadly ovate, as long as thorax but considerably broader. General color very dark metallic blue-black; antennae brown with whitish pile; legs with all femora and coxae blue-black; all tibiae and tarsi yellowish white; last tarsal joint dusky. Length, 1.28 mm . ; expanse, 3 mm .

Of this species I have seen 12 males all reared from chrysalis of Thecla calanus, presumably by Mr. Scudder.

## Tetrastichus modestus sp. nov.

Female.-Smooth, no perceptible punctation. Antemae arise slightly above clypens; scape reaches a little more thau half way to top of eyes; flagellum, nsually bent upon scape, reaches slightly below mouth; flagellum and especially club quite hairy. Mesoscutum with no median longitudinal sulcus; mesoscutellum with usnal sulci; submarginal vein with two strong bristles. Ablomen rather longer thau thorax, but not as broad, narrowly ovate in form. General color shining black, with very slight greenish reflections; auteunae brown, with whitish pile; wing veins very light brown; all cosae, femora and tibiae dark brown, the cozae and femora sometimes black and glistening; femero-tibial articulations and tips of all tibiae yellowish white; all tarsi yellowish white. Length, 1 mm .; expanse, 2.4 mm .

Male.-Differs from female only in having a slightly longer scape, and longer, more hairy flagellum.

Deseribed from four female, six male specimens reared by Mr. W. II. Edwards at Coalburgh, W. Va., from cocoons of Apanteles cdwardsii Riley, spun by larvae which had issued from Vanessa atalanta, and from Apanteles cocoons, the adults of which have not been bred, but which were spun by larvae which issued from the larvae of Polygonia interrogationis. All of these species of Tetrastichus are secondary parasites. No Tetrastichus, so far as known, is a primary parasite. The real host of none of Dr. Packard's is known. That of modestus is as indicated.

## Genus TRICHOGRAMMA Westwood.

Tarsi 3-jointed; front wings with regular rows of hairs, submarginal vein reaches costa, and, with margiual and stigmal, forms a regular arch; antenuae 8-jointedscape, pedicel, ring-joint, funicle (2), club (3)-; ring-joint very minute; funicle joints in female small and subequal in length and width; club large, obliquely truncate at tip. Iu the male the funicle joints are much larger and the club is of same width, tapering gradually to rounded tip.

Four described North American species, and a number of undescribed species have been examined, but it seems impossible to find structural charaeters of specific value. Certain series of individuals ean be distinguished by color, and by color alone, and for convenience those reared from butterfly eggs are grouped into the following species. The specimens should be mounted in balsam and should be studied with a dark background and reflected light, as the dusky tints are mainly lost with transmitted light. If mounted dry upon tags, these delicate insects shrivel to such an extent that they are useless for study.

## Trichogramma minutum Riley.

I have been unable to find recognizable specimens of this species. Speeimens preserved by Professor Riley, between two flakes of isinglass,
are spoiled. Structurally it is identical with the other forms. Colorationally it was described by Professor Riley in the following words: "It is inconspicuously marked, the body being dark brown, with the antennac and legs pale, and the wings iridescent.

The species was figured and described in the Third Report on the Insects of Missouri, p. 157, from specimens reared from the eggs of Basilarchia archippus in Missouri. From four to six parasites issued from each egg.

## Trichogramma minutissimum Packard.

Body uniformly pale testaceous or honey-yellow, legs and antenuae scarcely paler than the body. Abdomen a little longer than the thorax, but no wider, seen from above. Anteunae a little longer than in minutum, legs a little slenderer. Length, of .25 mm . to .37 mm . ; $; .38 \mathrm{~mm} .-.5 \mathrm{~mm}$. (After Packard.)
[The following description of the colors was taken during life:-Body and head wax-yellow; face a little paler; eyes and ocelli dark orange; body with jellow-green internal blotches appearing through the skin; legs aud auteunae pale jellow, apical half of tarsi a little dusky. s. II. s.]

In the material scut me by Mr. Scudder I find eight slides of this species, three labelled from eggs of Jasoniades glaucus, three from eggs of Basilarchia archippus, and two from eggs of Vancssa atalanta.

Trichogramma intermedium sp. nov. Pl. 89, fig. 8.
Male.-General color dirty yellow in effect; face bright yellow, eyes and ocelli red, antenuae slightly dusky; mesonotum very light yellow-gray; metanotum yellow; abdomen above slightly darker than mesonotum; all coxae dusky, hind femora slightly dusky above, remainder of legs dull yellowish. Wings with a slight cloud below submarginal vein. The nearly straight line of hairs runuing downwards from tip of stigma consists of five hairs, the first one sometimes included in stigmal club, leaviug only four apparent in the row. Average length, .55 mm . ; average expanse, 1.0 mm .

Female.-Slightly smaller, and not quite so dark as male.
[The following description of the colors was taken during life: Honey-yellow, the abdomen pale and banded transversely with dusky; eyes and ocelli salmon-red; legs and antennae greenish olive; apical two-fifths of tarsi fuscous. s. H. s.]

Of this species Mr. Scudder has sent me six slides, four containing specimens reared from eggs of Aglais milberti, and two from eggs of Thanaos lucilius. Mr. James Fletcher has since sent me from Ottawa four specimens reared during the summer of 1888 , from eggs of Oeneis macounii.

## FAMILY PROCTOTRUPIDAE STEPHENS.

## Genus TELENOMUS Haliday.

[^14]
## Table of Species.

Male abdomen only three-fourths as long as thorax ................................................................
Male abdomen nearly or quite as long as thorax........................................................ .

## Telenomus graptae sp. nov. Pl. 89, fig. 9.

Male.-The nine funicle joints of the antennae are beaded and well separated, all joints subequal in width, joints 4 to 9 nearly as broad as long, joint 2 longest, joints 1 and 3 subequal, both shorter than 2, and longer than 4 to 9 ; club shorter than two preceding joints together, conical, sharply pointed. Thorax much arched and very finely pilose. Abdomen three-fourths as long as thorax. Color dark brown, nearly black, the abdomen darker than head or thorax; antennae uniform dark brown; all coxae and femora dark brown; front tibiae light brown, middle and hind tibiae dark brown; all tarsi dark honey-yellow; wing veins brown, well marked. Levgth, .875 mm .; expanse, 2.3 mm .

Female.-Differs from male only in antennae, in which the last three flagellar joints form a large club, the three joints well separated, and the last slightly obliquely truncate. From the basal joint of the club the funicle joints taper down in size for three joints.

Described from one male and one female. The male was reared by Mr. Scudder from an egg of Polygonia progne, and the female was captured June 15, by Mr. C. W. Woodworth on the White Mountains while in the act of ovipositing in an egg of Euvanessa autiopa. Both specimens are poorly mounted in balsam, and the characters are difficult to observe. Mr. Scudder has also sent a slide containing a single female Telenomus, which I hesitate, on account of its poor condition, to separate from this species. It was reared from an egg of Heodes hypophlaeas.

Since this description was written I have received another female from Mr. Scudder, which I cannot separate from this species and which was reared from the egg of Limochares tanmas collected at Nepigon by Mr. Scudder in the summer of 1888 . A single female was also reared from an egg of Polygonia interrogationis at Washington, August 6, 1887.

## Telenomus rileyi sp. nov.

Mate.-Proportions of funicle joints much as in graptae; club more oval and less acutely pointed; joints 1 and 2 of funicle much nore constricted at base than at apex. Thorax somewhat less highly arched than in graptae. Abdomen nearly or quite as long as thorax. Pile of thorax not distinguishable under a moderate power. Color black, abdomen highly polished; scape and pedicel of antennae bright honey-yellow; joints of funicle yellow below, dusky above, last three joints (club) clark brown; all legs, including cosae, bright yellow, verging upon orange. Wing veins faint, dusky. Length, 72 mm . ; expanse, 1.8 mm .

Described from three males reared by Professor Riley from eggs of Chlorippe clyton in Missouri.

## FAMILY BRACONIDAE.

## SUBFAMILY MICROGASTERINAE.

BY C. V. RILEY.

It is difficult to properly consider the Microgasters affecting the larvae of New England Rhopalocera without a careful revision of the whole group ; but, at Mr. Howard's request, I have prepared the following notes which may not be without interest.

In the "Notes on North American Microgasters" (Trans. Acad. Sc. St. Louis, Vol. iv, No. 2, April, 1881) I have shown that the species are more variable than had been up to that time supposed, and that even in the manner of forming their cocoons, as well as in the character of the cocoons, there may be considerable variation in the same species. A large amount of additional material obtained since the publication of that paper, and in most cases connected with the host, has served to complicate the whole question of species, so that their delimitation becomes at times almost impossible. In short, a careful study of this group, as of most other groups well and fully represented, confirms the idea of the nonexistence of species as such in nature, and renders it almost as easy to make a continuous series as to make well marked divisions. On the present occasion, however, it is not necessary to enter into a consideration of this general subject of species, except in so far as to warn the reader that the species here treated of are characterized as such more for convenience than anything else; that if I have avoided a strong disposition to lump and combine forms hitherto considered good species, it is purely to assist in recognizing the alliances ; and that the average characters of assemblages rather than individual characters have been utilized.

In the terminology of parts there is need of greater precision than American authors, including myself, have hitherto employed; but I have often used scutellum for the prominent triangular piece, strictly the mesoscutellum ; and postscutellum when including the more critically differentiated mesopostscutellum, metapraescutum and metascutum, as the characteristic fovea usually extends across this last. Metascutellum is used for the larger piece, which I have heretofore called the metanotum. In the genus Apanteles I have begun with glomeratus, making the description of this species most full, for obvious reasons and for purposes of comparison.

The group is a difficult one on account of the monotony of the coloring
and slight structural variations. Ordinarily there are no striking secondary sexual characters, the male being on the average somewhat the smaller.

Where not otherwise stated, the rearing has been done by myself.

## Genus APANTELES Foerster.

Maxillary palpi 5-, labial 3-jointed. Antemae 18 -jointed. Eyes villose. Mesoplenrae impressed with a smooth fovea. Abclomen sessile; suturiform articulation distinct. Radins of fore wings subobsolete; 2 eubital areolets, the $2 d$ being open on the onter side, and thus confused with the 3t. Spurs of the hind tibiae never mneh shorter than $\frac{1}{2}$ the metatarsus. (After Marshall.)

## Table of Species.

Ovipositor long, as long as ahdomen.

## 1. Apanteles glomeratus (Linn.). Pl. 88, fig. 12.

Microgaster pieridis Pack.
Apanteles pierillivora Riley.

## Parasitic on Pieris rapae and P. oleracea.

Up to the publication of my paper already alluded to, it was not definitely known that this species occurred in North America, and I have already recorded (Ann. Rept. Entom., Dept. Agr., 1884, p. 323) the success of my efforts to colonize the species at Washington from cocoons received from Mr. G. C. Bignell of Plymouth, England, earlier attempts
which I made having failed. The importance of the introduction of this, one of the commonest parasites of Pieris rapae in Europe, and the interest attaching to it justified the trial. But for the last few years I have received many specimens, particularly from different parts of this country, of a Microgaster bred from Pieris rapae which bore a suspicious resemblance to the European glomeratus. The material before me includes, 1st: (from Europe) a perfect female which was received in 1879 by Mr. Howard from Dr. Gustav Mayr of Vienna; a large series in my own collection in the National Mnseum reared from the cocoons received from Mr. Bignell from England; other specimens descended from these last and reared in the District of Columbia, and two bunches of cocoons from Mr. Scudler collected in Europe in 1872; 2d: (reared from Pieris rapae in the United States) specimens from Prof. J. A. Lintner of Albany, N. Y., Mr. G. Haley of Brownfield, Me., Mr. E. W. Allis of Adrian, Mich., Prof. A. J. Cook of Lansing, Mich. and Mr. W. B. Alwood of Columbus, O., and finally four authoritative specimens of Microgaster pieridis (Pack.).

A careful sturly of all these specimens makes it impossible to separate the American bred forms from the European, from which fact it would seem evident that other importations must have taken place of late years besides that purposely made which I have already referred to. Indeed, as we shall see in considering the common and wide-spread congregatus (Say), one would be perfectly justified in looking upon it as an American representative of glomeratus, and while its different habit, and the slight differences which I point out make it possible and desirable to keep them under distinct specific names, yet the differences might with perhaps equal propriety be regarded as varietal, especially as atalantae is intermediate between them.

Thus it becomes in a measure a matter of mere speculation as to whether the more typical glomeratus in America is an entomophagic derivative of congregatus modified from breeding again in Pieris rapae or whether it represents earlier importations from Europe. We must not wonder at this difficulty in separating specifically allied European and American insects, when zoölogists are yet discussing the specific relations of many of the higher animals common to both countries, and opinions differ among the most competent to express them. In this country glomeratus, so far as the material indicates, is confined to P. rapae, while in Europe it is reared not only from the larva of this butterfly, but also from that of Mancipium brassicae and other species.
Length of body, $9,2.6-3 \mathrm{~mm}$. Color black. Pilosity of head and thorax quite marked and white. Head with the punctation very fine, tolerably dense, but less so on the polished face and clypeus; a deep puncture or fovea each side at apex of the clypeus; face with two more or less well defined. slender carinae diverging from the base of the antennae forward, the space beticeen them generally depressed, and in some cases short striae diverging from the carinae; eyes brown; mandibles either pale brownish or
honey-yellow; antennae black, the lower side of the basal joint and base of the flagellum often brownish; palpi from pale testaceous to quite yellow; mesothorax coarsely punctate, polished and sparsely pubescent; median cariuae of metanotum complete but faint; scutellum polished, sparsely punctate; postscutellum very narrow, almost linear, with a central more or less circular, sometimes almost square fovea, having a central, longitudinal carina thickened at hase; metascutellum rather coarsely and densely rugose, with a (generally) well defined, slender, median carina; tegulae brownish to black; wing venation normal; costa, stigma and radial veiu quite dark brown, though occasionally lighter, the other veins paler ; curve of radial vein more or less variable, sometimes quite angular; legs honey-vellow; posterior coxae black, sometimes brownish beneath, the others rarely hrownish; tip of posterior tihiae either black or dusky or concolorous; hind tarsi generally dusky. Abdomen black, the two basal joints closely punctate, sometimes slightly rugoso-punctate; the first joint longer than broad, narrowest at base, gradually broadening posteriorly, the hase deeply concave and highly polished, and the apical angles generally somewhat rounded; a more or less well defined, median carina on the second joint; lateral margin of both and generally of the third, honey-yellow to reddish, this color extending ventrally over the whole of two and sometimes of all three joints; rest of abdomen black, highly polished and with sparse and slender white hairs, arranged dorsally in one irregular row to each joint; ovipositor but slightly extending beyoud tip-often entirely hidden from above according as it is extended or drawn up.

ठ. Not separable except by the sexual differences common to the group.
The coloration of the legs as well as of the basal abdominal joints varies, the coxac being sometimes concolorous, i. c., all dusky and the femora exceptionally having no duskiness. The mandibles vary from yel-lowish-red to piccous. Described from some 150 specimens.

In the most complete European description at hand (Nees ab Esenbeck, Hym. Ichn. Aff., i, 181, 1834) the basal joint of the abdomen is made to form a rectangulum, due to the fact that the narrowing, highly polished base is generally hidden bencath the metascutellum, while the typical form accords more with our exceptional specimens having unicolorous femora. None of the specimens before me have the yellowish or reddish color on basal abdominal joints so broadened dorsally as to appear rufous with two large, black spots as described by Nees for the male.

The cocoons are formed in irregular masses of about 20-100 or more. They are ovoid and vary in color from very pale yellow to bright sulphurycllow, the loose external and combining threads being generally the deeper in color, and the American specimens, as a rule, paler than the European. Nees describes them as pale testaccous. The color not only varies slightly but will depend upon the amount of exposure to bleaching weather.

I have pointed out (Am. Nat., 1882, p. 679) that Dr. Packard's name picridis is preoccupied in the same genus and that his species was to be looked upon as a variety of congregatus. I therefore proposed the varietal name pieridivora for it.

The four specimens at hand, as also his description (Proc. Bost. Soc. Nat. Hist., xxi, 1880-2, p. 26), so far as it goes, agree well with glomer-
atus, and should now be considered synonymous with this last rather than a variety of congregatus, as I was inclined to place it prior to the study of glomeratus.

## Apanteles congregatus (Say).

## Parasitic on various Sphingidae.

This species, as I have shown, (op. cit.) is extremely variable, having several entomophagic varieties which most authors would perhaps look upon as good species. It has not been reared from any of the Rhopalocera and is referred to here because of its close relationship to glomeratus; from which in its more typical form, it may be distinguished by the following characters:

More generally hairy. Face less polished, densely punctate and in place of the di. verging carinae, a small, polished tubercle near and hetween the bases of anteunae and sometimes a faint indication of a median carina. Mesoscutum less polished, rather densely punctate and more pubescent; metascutellum with the lateral and posterior carinae more sharply defined and a median carina more often indicated. Legs more often concolorous and rarely with tips of femora and of tibiae dusky and still more rarely black. Wings with a rather darker tinge.

## 2. Apanteles edwardsii n. sp.

## Parasitic on Vanessa atalanta.

#### Abstract

Average length, 2.6 mm . \& : Color black. Legs pale yellowish-brown. Pilosity sparse and white. Head: face with a more or less distiuct carina; auteunae piceous; palpi very light yellow. Thorax: metascutellum without carina but with posterior angles and slight elevation at middle of hind border rather distinct and polished; scutellum sparsely punctate and not more polished than the rest of thorax; tegulae light honey-yellow: wings normal, stigma and costa piceous, veins paler; radial vein angulated a little beyond middle: legs with all coxae and all trochanters honey-yellow; front and middle femora, tibiae and tarsi honey-yellow; hind femora honey-yellow, dusky at tip; hind tibiae honey-yellow, nearly black at tip; hind tarsi brownish. Abdomen: joint 1 with a longitudinal oval median fovea not extending to joint 2 ; joint 1 narrow, emarginate behind, side pieces piccous-brown; joint 2 transverse, broader than 1 and thrice as broad as long, the hind wider than anterior border; both 1 and 2 strongly punctate, 3 but slightly so at anterior border; ovipositor exserted, very long, extending more than the whole length of the abdomen, and yellowish-brown.

Approaches closely A. cacoeciae (Riley).
The cocoons are elongate, dense, pure white or varying to a dingy white, with scarcely any loose silk. The species has only been bred from young larvae.

Described from four females reared from atalanta by Mr. William H. Edwards.

## 3. Apanteles megathymi Riley.

## Parasitic upon Megathymus yuccae.

I repeat here the description already published (Notes, etc., pp. 9-10).
Apanteles megathymi, n. sp. Length of body, 3 mm , § 우. Black; palpi whitish, antennae piceous; legs red, the cosae, and in the males the posterior femora and tarsi and the tips of the posterior tibiae, black or piceons, in the females the tips of posterior tibiae and the posterior tarsi dusky; wings, including the stigma, hyaline; tegulae and nervures white, the costa aud the outline of the stigma testaceous. Mesonotum closely punctate, the punctures tending to unite to form striae, opake, the scntellum polished, sparsely punctate; metathorax finely reticulate, divided into larger areas by regular ridges, two of these ridges enclosing a median ovate-lanceolate area, there being no median earina. Abtomen as long as the thorax, narrowing towards base; basal joint, excluding the less chitinized sides, longer than broad, and longer than the second and third joints taken together, delicately sculptured and with some seattered punctures of larger size; remainder of the abdomen smooth; second joint very short, separated from the thild by a deep, but very narrow groove; the third joint twice as long as the second. The ovipositor is exserted and as long as the abdomen. The vein from the stigma forms with the basal vein of the areolet only a slight curve.

Described from many specimens bred from larvae of Megathymus yuccae received from South Carolina. The cocoons are spun in white masses, filling the silk-lined burrows of the Yucea-borer. The flies appear in April shortly after the time of appearance of the butterfly, and are more or less powdered with the waxy secretion of the caterpillar.

## 4. Apanteles limenitidis Riley.

Microgaster limenitidis Riley; Third chae Riley; Notes on N. A. Microgasters, p. 13. Rept. Ins. Mo., p. $1 \overline{5} 8$. Apanteles limenitidis Riley; Packard, Apanteleslimenitidis Riley, form flaviconProc. Bost. Soe. Nat, Hist.

## Parasitic on Basilarchia archippus.

This parasite commonly infests the last brood of larvae of Basilarehia archippus in Missouri, and as my original description was rather general, I have drawn up a nore full characterization :

Average length $\delta, 2 \mathrm{~mm}$; $; 2.5 \mathrm{~mm}$. Color piccous-black with white pubescence. Head: with a pereeptible but rery slight median facial elevatiou below antennae : palpi whitish or testaceons. Thorax: mesoscutum coarsely punctate and with a faint median carina obsolete anteriorly ; seutellum more polished; fovea of metascutum broad, subtriangular and with central depression: wings normal the basal vein of areolet but slightly angulate: legs with all coxae and trochanters black; front femora with basal half black; apical half honey-yellow (sometimes nearly all honey-yellow); front tibiae and tarsi honey-yellow ; middle femora dark brown above, tibiae and tarsi honey-yellow; lind femora black; hind tibiac with basal half honey-yellow, apical half brown, spur yellow; hind tarsi brown above, paler below. Abdomen with joints 1,2 and 3 punctate, the rest polished; 2 with a slight median carina; 1 and 2 yellowish at sides ventrally; ovipositor hidden.

The male differs but slightly, the front and middle femora being usually darker. One female has all legs yellow except extreme tip of hind femora.

Described from mumerous specimens reared from B. archippus and others (rar. flaviconchae) from cocoons found in fields infested with Leneania unipuneta.

The eocoons from archippus are from young larvae of autumn brood and are dull whitish, single and with little loosesilk. Those of form flaviconchae are pale yellow and in masses with a small amount of loose silk.

## 5. Apanteles lunatus (Pack.).

> Microgrster lunates Pack., Proc. Bust. Soc. Nat. Hist., xxi, p. 2 s (15s0).
> Parasitic on Pipilio polyxenes.

This species was described by Dr. Packard from a single female bred by me from Papilio polyxenes. Mr. Scudder is not able to find the speeimen, and hence I can only adopt Dr. Packard's deseription :

Body dull black, not shining, stout and thick. Head and antennae corered with an unnsually dense silvery pile, the antennae rather thicker than in M. piericlis; palpi pale testaceous; front rather broad between the eyes; thorax dull black; metanotum with no median ridge. First subcostal cell instead of being irregularly oblong, is much broader and irregularly pentagonal. Fore and middle trochanters black, legs deep honey-yellow with a slight reldish tinge, outer thind of tarsi pale brownish; hind femora reddish honey-yellow tipped with black, tarsi wholly black. Abdomen entirely black, graunlated as usual ontwo basal segments, polished beyond, a faint dull testaceous spot on mider side of first segment, not appearing above. Length, 18 inch.

I have one female in poor condition reared from polyxenes received from W. B. Thomas, of Athens, Ga. in 1885, which is apparently this species, and which is characterized by a minute tuberele on the face, by the sentellum being densely punctate and not polished and by the basal joint of palpi being black. The metascutellum has no carina but is heavily pilose. Abdominal joint 1 narrow, the hind border almost as wide as the joint is long, without earina, but with a strongly marked median tuberele, extending to anterior border of joint 2 , with both joints and basal part of 3 strongly rugose. Ovipositor but slightly exserted, the sheath extending lut a short distance beyond the tip of abromen.

The cocoons are single, dense, dull yellow and with but little loose silk.

## 6. Apanteles cyaniridis n. sp.

Parasitic on Cyaniris pseudargiolus.
Length, 2.8 mm . ㅇ : Pilosity sparse. Heal: face withont carina; palpi pale yellow. Thoras: mesoscutum with barely a trace of a carina; scutellum hardly more polished
and evenly and minutely punctate; the scapulae perfectly smooth and polished behind; metascutellum with the median carina divided around acetabulum; the lateral carivae starting each side of spiracle: wings normal, with stigma and costa very dark brown, the radial rein strongly angulated below its middle: legs with all coxae black; all femora and tibiae honey-yellow ; trochanters dusky at base; hind femora dusky just at tip; hind tibiae with a dusky band at tip; hind tarsi dunky except at bases of joints; basal joint darker than the rest. Aldomen without a trace of yellow; dorsal plate of joint 1 broader posteriorly than long; of joint 2 with a well marked median carina extending slightly upon joint 3 ; joints, 1,2 and bave of 3 well sculptured; ovipositor but very slightly protruding and not reaching beyond tip of abdomen.

Described from 3 specimens in my collection received from William $H$. Edwards. reared from Cyaniris psendargiolus.

The cocoon is white with a tinge of lemon-rellow and surrounded with considerable loose silk.

## 7. Apanteles argynnidis n. sp.

Parasitic on Argynnis cybele.
Length of body, 2-2.2 mm . Color black. Pubescence white and quite dense. Head: profusely punctate: face without median carina or tuberele; mandibles yellowishbrown, palpi whitish; eyes black; antemae black, often brown or ferruginous beneath. Thorax more coarsely and densely punctate than the head, and with no median carina on nesoscutum ; scutellum somewhat polished and sparsely punctate; fovea of postscutellum smatl, transverse, divided by a distinct median carina; metascutellum strongly rugose, with distinct median carina, the lateral ridges almost parallel, diverging somewhat anteriorly; tegulae brownish-black: wings hyaline; venatiounormal; costa dark brown, stigma and veins paler brown : legs reddish-yellow; all coxae black, anteriorand median tarsi paler, alnost whitish, brownish toward the end, their claws blackish; posterior femora and tibiae blackish toward tips: posterior tarsi dusky. Abelomen black; the two basal joints liensely and contluently punctate, the third less so, and only at its basal half; joint llonger than broad, the concavity at its base deep and similarly sculpturec; a faint indication of a median ridge on joint 2 ; flexible margins of the two ha-al joiuts scarcely apparent, somewhat yellowish or often almost black; remaining joints highly polished and sparsely hairy ; renter black; ovipositor and its sheaths scarcely projecting.

The cocoon is dense, narrow, smaller than in kocbelei; single or in small. exposed masses, dingy white, with a little loose silk surrounding.

This species also closely resembles A. flaviconchae, which differs, however, in being somewhat larger, in having a more densely punctate thorax and scutellum, in the entirely punctate third abdominal joint and in having the basal half of the anterior and median and the whole of posterior femora, black.

Described from 7 specimens, all females, bred from Argynnis cybele by William H. Edwards.

## 8. Apanteles koebelei n. sp.

Parasitic on Lemonias anicia.
Length of body $2.6-2.8 \mathrm{~mm}$. \& : color black. P'ubescence short, dense and faintly
yellowish. Head finely pnnctate, somewhat polished; facial carina not well detinect, but teminating in front of antennac in a distinct polished tuberele; mandibles redidish; palpi whitish, the basal joint of maxillary papi black; eyes brown with paled inner border; antennae black in both sexes, seareely as long as the botly. Thorue: scutellum polished, sparsely punctate; fovea of post-scutellum circular, occasionally with a rouncl, central granule; metascutum and metascutelium coarsely rugose, the median carina on latter distinct, the lateral carinae straight, diverging ante. riorly: tegulae blackisin: wings lyyaline, renation nomal; the radial rein angulated; costa, stigma and reins brownish black: legs, usually redulish with all coxae black and the extreme base of the anterior and median and aper of posterior femora more or less distinctly blackish; all tarsi more or less dusky. Abdomen black, laterally compressed beyond joint 3 , and wedge-shaped; joint 2 and extreme base 3 rugose-pnactate; joint 1 longer than broad, narrowest at base, broaleniug and almost as broad posteriorly as 2; concavity at base deep and not polished; median carina of joint 2 either very distinct or almost wanting; the other joints highly polished and sparsely hairy ; fiesible border of two basal joints rather narrow; renter black; the ovipositor short, easerted, its sheathis black.

The $\delta$ is distinguisled by the longer antenna, by the less compresseci abiomen, by the palpi being dusky, the femora darker, the sides black along the whole length, the tibiae with a dusky tinge and the tarsi backish. There is more variation in the carina on abdominal joint 2 , being but feebly indicated in oue specimen and wanting in a second.

There is some variation in coloration, and one female, smaller than the average, has the coloration of the male.

The cocoons are white, less satiny than in flavicornis, somewhat stonter, but similarly exposed and heh together by loose silk.

Described from 15 specimens ( $129,3 \delta$ ), bred by $M 1$. A. Foebele from Lemonias anicia? from California.

This species resembles A. limenitidis, var. flaviconchae which is readily distinguished, however, by the want of median carina and facial tuberele, hut its coarser and more densely punctate mesoscutelhm, the coarser sculptming of the basal abdominal joints and by the normally shaped abolomen.

## 9. Apanteles flavicornis n. sp.

## Parasitic on Thanaos juvenalis.

Average length of body 2 mm . $q:$ general color black; pubescence quite dense, short white. Head: face without carina or tubercle; manclibles honey-yellow; palpi white with the first joint of the maxillary palpi pale yellow; antenuae brown above, yellowish-brown beneath. Thorus: mesonotum without or rarely with an indication of a carina; scutellum polished, withont punctation; forea of postscutellum very small, divided by a minute median ridge; metascntellum rugose, its median carina distinct; tegulae yellow : wings with the costal, stigma and radial vein brown, the other veins almost colorless: legs honer-yellow, the posterior cosae black; tip of posteriur femora, tibiae and tarsi often dusky. Abdomen black and honey-yellow; basal joint somewhat longer than broad, narrowest at base; together with second joint and more or less of the base of the third, rugose-punctate; the second with a rather prominent metlian carina; the other joints polished; the margins of joints 1 and 2 , whole of 4 and 5 and generaily the posterior margin and angles of 3 and sometimes more or less of 6 and the greater portion of the venter honey-yellow; ovipositor very short, sarcely exserted.

I with the antennae entirely yellow and the ablomen above generally black.

The cocoons are narrow, satiny, pure white and spun in irregular masses loosely held together by some few threads, but not cmbedded.

Described from 17 specimens, bred from Thanaos juvenalis at Kirkwood, Mo.

The species is close to emarginatus, which is distinguished, however, by its larger size, by the black antennae (brownish beneath only in the male), by the frontal tubercle, the punctate scutellum, the coarser punctation of abdomen, the somewhat darker venation, and the cottony nature of the cocoon mass.

## 10. Apanteles emarginatus n. sp.

Parasitic on Euphoeades troilns.
Length of body, 2.4 mm . to 2.6 mm . I : general color black; hairs white, very short. Head: punctation moderately coarse and dense; face with a distinct median tubercle near base of antennae; mandibles reddish-yellow, their tips brown; palpi pale testaceous; antennae black, basal joint reddish-yellow beneath, with black apex. Thorax: with punctation on mesoscutum dense and coarse, and with an indication of a median carina at posterior half; scutellum somewhat polished and sparsely punctate; postscutellom as in glomeratus; metascutellum closely and quite coarsely rugose, with an indication of a median and with a distinct, angulated, lateral carina; tegulae testaceous: wings as in glomeratus: legs reddish-yellow; hind cosae dusky on basal half; extreme tip of femora and more or less of hind tarsi often dusky or blackish. Abdomen with the two basal joints opaque, and with the base of the $3 d$ densely and quite coarsely rugose; basal joint longer than broad, narrowest at base, which is not polished and only slightly concave; rest of the abdomen above highly polished and sparsely beset with slender white hairs; lateral margins of basal joints 1 and 2 , a quite distinct, roundish spot each side of the 3 , and the greatest portion of venter, reddish yellow; ovipositor with the onter sheaths black and stout, and reaching about 1 mm . beyond tip of abdomen.

I with the antennae more or less distinctly brownish beneath.
Described from 7 specimens marked from troilus by Mr. A. Koebele, in breedings at the Department of Agriculture; but as I have no notes other than the label, I feel some uncertainty about the host. In general appearance the species approaches scitulus, which is readily distinguished, however. by the absence of facial tubercle, coarser sculpturing and more yellow abdomen and legs.

The cocoons are very delicate, white and imbedded in a dense mase of white, cottony silk, laving a faint yellow tinge.

## 11. Apanteles theclae Riley.

Parasitic on Thecla sp.
This species, described in my "Notes on N. A. Microgastere" (loc. cit.) has several times been reared by me from the larva of a Thecla found in Georgia and Alabama upon the cotton plant. The butterfly has not been
reared, and as it may prove to be a species foumd in New Englaml, the description of the parasite is here quoted :-
A panteles theclae: length 2 mm. ठ. \& black; palpi white; labrun, mandibles, aud sometimes the antemnae, piceons; tibiac and tarsi testaceons, the apical half of posterior tibiae and the posterior tarsi hlackish. Wiugs hyaline; the tegulae, stigma, costa, beyond stigma, and the radius and veins at base of areolet, piceous. Antennae of the female much shorter than the body, of the male nearly as long as the body. Mesothorax closely punctured, opaque; metathorax not truncate, finely rugosereticulate, and with a slight median, longitudinal ridge. Two basal joints of the abdomen with numerous distinct punctures; remaining joints often sparsely puctate; basal joint with the lateral margins narrow; ovipositor not exserted. Stigma short, triangular, radins descending from its middle and uniting at a considerable angle with the basal rein of the areolet.

## 12. Apanteles junoniae n. sp.

## Parasitic on Junonia coenia.

Length of body J, 2.6 mm . Color black. Punctation of head, thorax and scutelIum clense, coarsest on thorax, very deuse, fine and somewhat confluent on the head. Head with facial ridge not very distinct, though there is a slight, smooth projection close to and in front of the antennae; (palpi wanting) eyes brown; autennae black; the first joint and flagellum brownish beneath. Thorac with a slight mediau carina on posterior third of mesoscutun; fovea of postscutellnm minute; metascutellum rugose, without mediau carina, its lateral carinae strongly angulated; tegulae honeyyellow: wings norinal ; costa brown, stigma yellowish brown, veins very pale yellowish: legs brownish-yellow, with all coxae black and posterior femora dusky. Abdomen black, of normal shape; joint 1 slender but slightly broader posteriorly than at base, and much narrower than 2, sides broadly bordered by a flexible, honesyellow margin; the three basal joints sculptured. 1 and 2 densely and 3 less so; no median carina on 2; the other joints polished; venter honey-yellow as far as joint 3 .

The cocoon is single, dense, yellowish-white, and covered with threads of loose silk.

This species closely resembles A. carduicola Pack., but differs from it in several points, more particularly in the shape of the first abdominal joint, which in carduicola is posteriorly almost as broad as joint 2, and which has the third joint smooth, the yellow borders almost wanting and the middle and posterior legs much darker.

Described from a single specimen, bred from Junonia coenia.

## 13. Apanteles carduicola Pack.

## Parasitic on Vanessa cardui.

Microgaster carduicola Pack., Proc. Bost. Soc. Nat. Hist., Xxi, p. 27 (1880).

## Its characters are as follows :-

Average length, 3 mm . Head black; palpi pale testaceous. Thorax moderately and uniformly punctate; the metascutum without carina; the scntellum more highly polisbed; fovea of postscutellum broad and with a central pit; metascntellum without carina. Abdomen with ovipositor just showing at tip of body; dorsal plate of
joint 1 narrowest at base, its lengtle exceoding its wilth at hind border, its lateral elges slightly arcuate and rounded behind; joints 1 and 2 rugose; rest of ablomen perfectly smooth, polished and with little trace of hairs; the radius of wings normal; stigma rather broad; radial vein strongly angled; cosae and trochanters black; basal one-third to one-half of front femora blackish, rest ferruginous and concolorous with tibiae; tarsi brownish, base of first tarsal joint paler; middle and hind femora blackish; tibiae ferruginous, with a slight dusky tinge; tarsi pale at base, becoming black towards claws.

11 speeimens, all $\circ$, are before me bred by Mr. Scudder from Vanessa cardui, but no cocoons accomp:my them.

The species elosely resembles Apanteles thectae Riler, but may be distinguished by having no median ridge on metascutellum, by the more closely punctate basal joints of abdomen, by the slightly larger size, by the more intense angulation of the radial rein, the lack of punctation beyond the second abdominal joint, and in the almost complete absence of hairs from the abdomen.
14. Apanteles atalantae Packard. Pl. 88, fig. 13.

Parasitic on Vanessa atalanta and Aglais milberti.
Dr. Packards colorational deseription (Proc. Bost. Soe. Nat. Hist., xxi, p. 27) which would apply to many different forms is as follows:
"Body jet black, polished; antennae blackish brown; palpi whitish; mandibles pale reddish, blackish at base. Legs with the coxac black; trochanters blackish at base, all beyoud dark honey-yellow; terminal joint of tarsi a little dusky."

From limited material and the description I formerly considered this a variety of congregatus (Am. Nat., 1882, p. 670) ; but from a larger number of speeimens since examined it may rery well remain as a good species, intermediate in some respeets between glomeratus and congregatus by comparison with which it may best be charaeterized.

From glomeratus it differs in the more convex, more densely punctate face without diverging carinae; in the lateral ridges of metathorax being more clistinet. From congregatus it differs in being less hairy, in the less densely punctate face withont distinet tuberele, and in its concolorons coxac. From both species it is distinguished by the smoother sceond joint of abdomen, the sculpture being confined to thelateral borlers; by the stigma being shorter and darker, the angle of the radial vein more pronomed and above the middle of the vein, i. e., nearer to the stigma ; and finally by the sheath of the ovipositor being broader, more strongly developed and projecting somewhat more beyoud the tip of abdomen.

In some specimens, the midalle portion of the first abdominal joint is also smooth and impunctate.

I have examined some 50 specimens from atalanta and 15 from milberti reared by Packard, and 2 specimens from milberti reared by William H. Edwards. There are no entomophagic differences whatever in the specimens.

The cocoons are arranged on end, side by side, in morlerate masses, the whole covered with lonse silk and the eolor pure white.

## 15. Apanteles pholisorae n. sp.

## Parasitic on Pholisora eatullus.

Lencth of body, $2.4 \mathrm{~mm} .-2.7 \mathrm{~mm}$. \& : Color black with much reddish-yellow on abdomen. Pubescence rather dense and white. Head: punctation coarse and uniform ; a deep puncture on each side of clypens; facial carina quite distinct; mandibles yellow-ish-hrown; palpi pale testaceons; eyes brown, antennae black, longer in the male than in the female, the basal joint of ten yellowish-brown, and the flagellum beneath, in both sexes frefuently brownish. Thoras: scutellum sparsely punctate ancl somewhat polished; postscntellum very narrow, its median fovea small and often indistinct; metascutellum rugose, its median carina distinct, the lateral carinae straight and parallel with it ; tegulae brownish : wings normal, the radial vein variable and either uniformly curved or more or less angulated; costa, stigma and radial vein light brown, the other veins paler: legs honey-yellow; anterior and median coxae brownish, the hind pair black; hind femora and tibiae blackish at tip; all tarsi slightly dusky, the posterior pair clarkest ; claws blackish. Aldomen narrow, slender, tapering gractually from joint 2 toward the encl ; basal joints 1 and 2 black and closely punctate; joint 1 longer than broad, narrowest at base, broadening grachally toward hind border where the angles are slighty rouncled, the basal portion somewhat concare; joint 2 with a rather distinct median carina; remaining joints polished and sparsely hairy, their color variable, either entirely honey-yellow, with only the sutures blackish or with only 2 yellowish spots at the hind border of 3 , with all gradations between these extremes; flexible lateral margin of 1 and 2 and often the whole venter, honey-yellow; sheath of ovipositor black and reaching somewhat beyond the tip of abciomen.

Resembles both A. seitulus and A. emarginatus. From the latter it is distinguished by the absence of the facial tuberele, by the denser and eoarser seulpturing of the head and absence of median earina on posterior half of mesoscutum ; by the median carina and straight lateral ridge on the metascutum and the more slender abdomen. From seitulus it differs in the smaller size, the more slender abdomen, with its earina and different sculpturing.

Described from 16 specimens, reared from Pholisora catullus, one by William H. Elwards, the rest by myself.

The cocoons are normal, perfectly white, with much loose silk adhering to them, and either single or in small masses.

## 16. Apanteles cassianus Riley.

## Parasitic on Xanthidia nieippe.

This species was described by me (loc. cit., p. 12) from cocoons found at East St. Louis, Ill., upon Cassia marylandica with Xanthidia nicippe from which they had in all probability issued. I reproduce the deseription:

[^15]cepting at the apex and on the apical half of the basal joint of posterior pair, whitish; the anterior femora more or less piceous and the intermediate tibiae often tinged with testaceons. Wingshyaline, the veins white; the stigma, strongly in contrast, piceons; tegulae tipped with piceons. Antennae of the of scarcely shorter than those of the $\delta$. Mesothorax opake, the punctures slallow and obscure; metathorax opake, without distinct scupture, its upper face limited oneach side by a carina exterior to the spiracles, a few slight ridges at the apex. Abdomen without punctures, lateral margins of the basal joint dark piceons, the central portion broad and with sharply defined sides; second joint with a broad, triangular central area marked oft by two deep grooves which diverge from the middle of the anterior margin; ovipositor concealect. The radius forms with the basal vein of the areolet only a slight curve, but in one or two specimens there is a slight angle on the outer side at their point of union."

Since the description was published I have received two other specimens, one reared from nicippe, by Mr. William H. Edwards and one from Eurymus eurytheme by Mr. David Bruce in Colorado. The species is well marked especially by the scnlpture of the second abdominal joint. The cocoons vary. Those from which my specimens were obtained are either dingy gray or pale yellowish, the former with five tolerably markel longitudinal ribs, the latter almost smooth. That from Mr. Edwards is intermediate.

## Genus MICROGASTER Latreille.

 rae rarely with a rugulose forea. Abdomen sessile; suturiform articulation distinet. Radins of the fore wing almost complete; three arbital areolets, the 2 l often imperfect. IInd coxae elongate; spurs of the hind tibiae not shorter than half the metatarsus. Terebra more or less exserted. (After Marshall.)

Microgaster carinata Pack. Pl. 88, fig. 11.

## Parasitic on Vanessa atalanta.

Microgaster carinatul'ack., I'roc. Bost. Soc. Nat. Hist., xxi, p. 25 (1880).
This species was deseribed by Dr. Packard from specimens bred by Mr. Scudder from Vancssa atalanta. Its characteristics from the material before me, rather than from the original description, are as follows:

Average length, 4 mm . $f:$ Body black. Antennae brownish-black; palpi pale yellow. Wings with the stigma and veins brown. All coxae black; all trochanters black at base and yellowish at tip; front and middle femora, tibiae and tarsi honey yellow; the tarsi draky at tip; hind femora and tibiae honey-yellow and dark at tip; hind tarsi dusky throughont. Abdomen with dorsum of joints 1 and 2 strongly rugose, the rugosity on joint 1 having a tendency to form into irregular, longitudinal lines towned the onter hind angles, the median carina being obsolete but with a decided eleration or tubercle on the hind border; anterior portion of joint 3 very slightly punctate; ovipositor quite long, reaching when extended beyond the length of the whole abdomen; the sheaths dark, quite pilose and two-thirds as long as abdomen. Fenter with a large, honey-yellow spot each side at base.

Three females are before me from Mr. Sculder.
In my notes on Microgasters (Am. Nat., Aug. 1882, p. 679). I have
stated it to be a variety of M. gelechiae (Riley) having then seen but one specimen. With the material before me it may, however, stand as a species, for, in addition to the colorational differences there pointed out and to the other colorational fact that in gelechiae the yellow spot covers nearly or quite the whole of the dorsum of joints 5 and 6 , structural differences are also noticeable in that the rugose elevations of first tergite in gelechiae exhibit no tendency toward forming longitudinal lines behind and that the scutellmm is much more strongly punctate than in carinata. The sheath of ovipositor is, also, less pilose.

## THE

# DIPTEROUS PARASITES 

OF

NOORTH AMERICAN BUTTERFLIES.

By s. W. WILliston, NEW hayEN, CONN.

> But when he spide the joyous Butterflie In this faire plot dispacing to and fro. Feareles of foes and hitden jeopartie. Lord! how he gan fur to bestirre him tho, And to his wicked worke each part applie: His heart did rearue against his hated foe, And bowels so with rankling poyson swehe, That searee the skin the strong eantagion hede.
> Spexser. - Muimpotmos.

Not many species of Diptera are known to be parasitic tipon butterflies, either in Europe or America, and they are all, with the exeeptions noted below, included in one family, the Tachinidae. In Europe, about fifteen species have been bred and recognized, belonging to the genera Tachina, Masicera, Exorista, and Phorocera. Others have been described by Robinean Desvoidy, but the diffienlty, if not impossibility, of recognizing this author's species detracts almost wholly from the valne of his observations. Doubtless there are many more to be recognized in Europe, yet we can hardly expect as large a number as in North Ameriea, for the reason that there is a greater diversity in the butterfly fanna of our country. All the species that are now known as true parasites upon our butterflies are ineluded in the following lists. It will be noticed that they all, with one exception, belong to the same genera as do the European species. Masicera is sometimes difficult to distinguish from Tachina, in its narrowest sense; the three species described below, from the length of the third antennal joint, I have no hesitation in referring to Masiecra. As several of the butterflies upon which some of the flies are parasitic are either cosmopolitan or introduced, it is not at all improbable that the parasites may, in the future, be found to be identical. As everyone who has given any attention to the Tachinidac is aware, the description of a speeies is insufficient to base a positive determination upon when the observed habitat is a remote one, and nothing more than an opinion can be hazarded till an actual and elose comparison is made of specimens. Further, it is to be borne in mind that the identity of the host is only of negative value in
the determination of the parasite; while one may, with much probability, assmme that a fly bred in America from Vanessa atalanta is Exorista futilis, yet it may be quite another species, and E. futilis may, with much probability, be also parasitic upon some other butterfly or moth. Phorocera concinnata Meigen has been found parasitic upon five species of Vanessidi and two species of Pieridi. So, also, Exorista vulgaris Fallen has been bred from Pieris rapae, Cinclidia athalia, Procrustes coriarius and Plusia gamma.

Two species of flies belonging to very different families have been sent me as haring been lired from butterfy larvae. One of these, a species of Phora ( $89: 16$ ), may have becn parasitic upon the living larva, but, more frequently, the larvae of these flies are found in decaying animal or vegetable matter. I cannot recognize the species among those hitherto described, and the preservation of the specimen will not warrant its description as new. The other, Syneches pusillus Loew, I was surprised to find, among the speeimens sent by Mr. Seudder, bearing the label "Lyc. neglecta larra," with the chirography apparently that of Mr. W. H. Edwards. That there might be no error, however, I sent the specimen to that gentleman, who assured me that the label was his, and, furthermore, though he conld not reeall the specimen, that there could be no possibility of donbt in the labelling of the specimen, as indeed no one could suspeet from Mr. Edwards's known reputation. The fact is one of much interest, as I cannot learn that any species of this family (Empidac) has hitherto been known to be parasitic in the larval state, though the members are pre-eminently predaceous in the adult stage. So far as I am aware, the known species of this genus are confined to Enrope (Pterospilus), Africa, and America. A possible, if not probable, explanation of the parasitism in the present case is, that the larva had entered the butterfly caterpillar or chrysalis after hatching. The larvae of Empidae, so far as known, live in decaying wood, humus, etc.

The larvae of Tachinidae will be recognized by their headless, maggotlike appearance. They are thick, cylindrical, flattened below, the segments distinctly separated, with transverse and side swellings, either naked, or girdled with thin, short spines; the antennae are thick, wart-like, and the mouth has two, slightly eurved, projecting hooklets. The pruparium, formed by the larval skin, is elongate ellipsoidal in shape, of a deep brown or reddish brown color, with the ends obtusely rounded, the segmentation only feebly indicated, moderately smooth, without projections, save the two obtuse stigmatic tubercles at the hind end. The flies, it is needless to say, are cyclorrhaphous, that is, they escape from the pupigerous larral enyelope throngh a circular opening made by bursting off the anterior segments.

In addition to the species described below, there were sent me by Mr.

Scudder a very much injured specimen of Phorocera from Cinelidia harrisii and a puparinm from Polygonia comma.
[A detailed account of the actions of a Tachina in laying her eggs upon a caterpillar is given by Mr. A. C. Weeks (Ent. Amer., iii, 126).]

The following list of the European dipterous parasites of butterflies makes no pretensions to completeness; it contains all the references that I have been able to obtain with the resources at my command. Indeed, as it is, the mumber of references is chiefly due to the very great kinduess of Professor Mik. Such a list, even were it quite complete so far as the literature is concerned, loses, alas, much of its value from the fact that not much reliance can be placed on the specific mames of some of the authors. The yet unraveled synonymy, especially in the parasitic genera, of the European Tachinidae is frightful. May it never reach such a state in Ameriea! It is greatly to be regretted that we know so very little of this family of flies, perhaps the most important among all insects in its economic relations, in our own country. But, mentil the time shall arrive when a better knowledge is possible, may the heedless describer beware!

## Table of species of dipterous parasites.

Proboscis slender, horny, projecting beyond the oral margin, with small labella; eyes hare..... Acroglossa hesperidarum.
Proboscis short, fleshy, with broad labella.
Eyes bare; palpi yellow; second abdominal segment without anterior pair of bristles (Masicera).
Second abdominal segment with a pair of posterior bristles.
Antennae and abdomen wholly black ( \& \& ) ; claws and pulvilli of male elongate... M. frenehii.

Third antennal joint at the base, and the sides of the abdominal segments largely red; claws and pulvilli of male not clongate..................... M. archippivora
Second segment without bristles; ablomen on the sides broadly red............ rilesi

Eyes pubescent.
A row of well developed bristles on the lateral margins of the faeial depression reaching nearly or ruite to a point opposite the lowermost one of the frontal rows (Phorocera).

Antemac black; abdomen shining, the sccond segment with thrce pairs of bristles,
the third with two pairs before the hind row....................... P. sanndersii.
Palpi and antemare more or less ycllow; second ablominal segment with not more than two pairs of bristles.

Second and third abdominal segments with a pair of bristles toward the front; claws and pulvilli of male small. . P. eomstoeki.
Second and third segments withont anterior pair of bristles, the posterior bristles strong. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . .P. edwardsii.
Above the vibrissal bristle, near the oral margin, there are ouly a few small bristles (Exorista).

Palpi yellow.
Abdomen at sides and tip brokelly red; legs black................. . E. sendderi.
Abdomen withont red on the sides.........................................E. Blanda. Palpi black or dark brown.

Second abdominal segment with a median and posterior pair of bristles; abdomen in general bristly........................................................... $\mathbf{E}$. hirsuta.
Second segment with a posterior, but no median pair of bristles.
Abdomen black, marmorate with silver gray, the fourth segment brassy
Fellow pollinose........................................................... . . . futilis.
Abdomen largely shining black, no yellow pollen on the fourth segment...
E. theelarimi.

## ACROGLOSSA, gen. nov.

Allied to Froutina, but differs in the distinctly jointed arista, and in the slender proboscis. Front broad in both sexes, a little narrower in the male, nearly straight longitudinally, and but little convex transversely; arrangement of the bristles in the male, as follows: Two bristles near the upper angle of the cye, directed posteriorly; a pair just in front of the ocelli, directed exterionly and anteriorly; two rows of moderately strong bristles on eacli side, the inner row descending on the sides of the face as low as the base of the third antennal joint. In the female, there is, in addition to the foregoing, two or three bristles on each side near the eye, directed anteriorly. Antenuae rather slender, reaching nearly to the oral margin; third joint in the male fully three times, in the female scarcely twice, as long as the second; arista thickened nearly its whole length, distinctly jointed, the second joint long, and forming with the distal joint a more or less distinct angle. Margins of facial depression with a row of modcrately stout bristles, reaching nearly as high as the base of the third antenual joint; sides of the face with bristles; cheeks withont bristles, a row along the oral margin. Proboscis slender, horny, with small labella, projecting a short distance beyoud epistoma; palpi slender, cylinirical. Eyes bare. Scutellum with three pairs of marginal bristles of nearly equal size; a smaller pair on the disk. Abdomen conically ovate, elothed with short, bristly hairs; secoud segment with a pair of stout bristles on the posterior margin; third and fourth segments each with a posterior row. Pulvilli of male elongate. First posterior cell open at some clistance before the tip of wing; great cross-vein nearer to the angle of first posterior cell than to the anterior crossvein.

The relationship of this genus is closest to Frontina, to which it bears not a little resemblance in the broad, bristly front and general appearance; the structure of the arista and proboscis, however, will immediately distinguish it.

## Acroglossa hesperidarum Harris, MSS. Pl. 89, figs. 21, 26.

Male, fomale.-Front with a golden yellowish cast; face silvery white, the gronndcolor on the oral margin yellow. Antemae black, the first two joints and immediate base of the third yellowish red. Palpi reddish yellow; proboscis black. Mesonotum thinly pollinose, with fonr, rather broad, slining black stripes. Scutellum broady reddish ycllow. Abdomen black, with a broad, variable, gray, pollinose band on each segment; extreme tip red. Legs black. Wings grayish hyaline. Leugth, 1l-12 mm.

Two specimens, from the Boston Society of Natural History, labelled, apparently by Harris, "293, N. H.," and bred by him from Epargyrens tityrus. The sides of the face in the male are scarcely a half the width of the median depression; in the female they are three-fourths or more as wide, the depression being smaller, and the sides wider. This, or an allied species, is not rare in collections.

## Exorista futilis Say. Pl. 86, fig. 10.

Tachina (Exorista) futilis (Sar) Osten Sacken, Canadian Entomologist, xix:161 (1887).
Male, femcle.-"Bottom of the antennal foveae silvery gray; the lower part of the cheeks likewise; lateral part of the face and the orbit of the eyes below and behind (genal and occipital orbit) brassy-jellowish, the coloring of the front being of a more saturate yellow than the lateral parts of the face; above the antemae, in the middle of the front, a brown stripe, attenuated posteriorly; it bifurcates on the vertex, enclosing the grayish, ocellar triangle; the hind plane of the head (occiput) gray. The row of frontal bristles consists : first, of three bristles pointing backwards, the uppermost of which is placed on the top of the vertex; second, of three shorter bristles pointing forward; third, of four or five bristles, which form diverging rows, descending on each side of the antennae, the last being a little below the end of the scond antennal joint. Between the frontal bristles and the eyes, the front bears numerons little hairs; between these rows, on the ocellar triangle is the nsnal pair of bristles pointing forwards. The females have three supernumerary pairs of larger bristles, the first is placed behind the upper corner of the eye, the other two between the frontal row and the orbit of the eye. Among the above described smaller hairs, immediately below the last bristle, the brassy yellow color of the face shows a brown, changing spot, visible in an oblique light only; below this place, the lateral parts of the face are smooth; a short distance above the oral margin there is, on each side, the usual long bristle; above it, some shorter hairs reach to about one-quarter of the clistance between the long bristle and the root of the antennae. Antennae black; second joint with grayish pollen, and with a crest of short, stiff bristles; third joint long, with parallel sides, more than three times the length of the second, not quite reaching the edge of the month. Eyes distimetly pubescent. Ground color of the thorax bluishblack: almost concealed by five stripes of gray pollen, with intermediate black lines; the gray stripes are especially apparent when viewed obliquely from the posterior end of the body; in this light the median stripe appears bifnrcated posteriorly; the next pair abbreviated posteriorly; the lateral pair very broad anteriorly, over the humeri. Scutcllum bluish-black, with gray pollinose reflections; its tip faintly brownish [or red]; on the hind edge there are six [or eight] bristles, the intermediate [apical] pair the shortest; above this pair, on the plane of the scutellum, another similar pair. Pleurae grayish pollinose. Abdomen black, marmorate with silvery gray; the fonrth segment brassy yellow [pollinose]. The whole abdomen is covered with dense, short hairs; a pair of longer bristles near the lind margin of the first and second segments; a row of such bristles on the hind margin of the third segment, and a double row at the end of the fourth. Legs black; pnlvilli brown; knees slightly brownish. Wings : the first posterior cell open (closed by the prolongation of the costal vein, however, which
nearly reaches the apex of the wing) ; the distance between the tips of the second and third veins is a little longer than that between the third vein and the apex of the wing; the elbow of the fourth vein without stump of a vein (a very minute one in one of the specimens) ; the great cross-vein oblique, parallel to the last section of the fourth rein; small cross-vein (in most specimens) opposite to about the middle of the distance between the tips of the anxillary and first vein, Length, 7 mm ."
[The following description of the early stages was taken from the living specimens : -Larva yellowish white, tapering anteriorly and armed with a clouble curving black hook; blunt posteriorly and furnished with a pair of black circular warts each hollowed and having the annular ridge thus produced elevated into three slight prominences. Length, 13 mm . ; breadth, 4 mm .; height, 3.25 mm .

The pupa case is short and thick, bluntly and equally rounded at either end; at the posterior extremity are two minute warts scarcely raised above the surface; on either side are two distant irregular rows of nearly continuous, longitudinal punctures; at the posterior end of each segment, oecupying nearly one-third of it, is a band of minute raised points arranged to a certain extent in diagonal rows; the remainder of the surface is finely striated with transverse lines and also marked by shorter impressed lines, radiatiug from points on either side either connected with the two longitudinal rows of punctures or lying between them. The color is very dark reldish black, almost piceous. Length, 8.76 mm . ; breadth, 4.4 mm . s. 11. s].
"Bred from Vanessa atalanta (T. W. Harris and S. H. Scadder)."
Several bred specimens sent me by Mr. Scudder and others collected in the vicinity of New Ilaven, agree well with the type speeimens of Osten Sacken; the only differences that I would note are included within the brackets. Very characteristic of the species is the changing spot on the sides of the face below the antennae.

Exorista blanda Osten Sacken. Pl. 89, fig. 11.
Tachina (Esorista) blande Osten Sacken, Cantlian Entomologist, xix: 162, 1857.
"Male.-Distribution of the frontal bristles as in E. futilis $\delta$, that is, on each side, beginning with the vertex, three longer bristles pointing backwards, three shorter bristles before the antenuae, and three or fonr bristles descending on the face, alongside the antenuae. On the ocellar triangle a pair of bristles pointing forward. Between the row of frontal bristles and the eyes, a few scattered microscopic hairs; sides of the face bare. Front, face, and posterior orbit silvery white. Frontal stripe brown, rather narrow, enclosing posteriorly the grayish ocellar triangle. Antennae black, slightly tinged with brownish red on the first two joints; the third joint is very long, almost reaching the edge of the mouth. Only a few shorter bristles above the usual long, oral bristle. Palpi reddish yellow. Eyes pubescent. Thorax gray, with a slight yellowish tinge from an oblique point of view; two slightly divergent black lines do not reach beyond the middle; two lateral black stripes are interrupted at the suture and prolonged beyond it to the lind border, these lateral stripes are broadest in the middle and eud in a point, anteriorly and posteriorly. Scutellum gray; two [larger and a smaller] macrochaetae on each side, a third intermediate, very small pair on the apex. Abdomen gray, with a slightly yellowish tinge, especially on the last segment; somewhat marmorate, with blackish cross-bands on the hind margins of the segments, and a longitudinal blackish line; the eross-bands appear more distinct and broader from an oblique point of view; the longitudinal line disappears when viewed sideways from above. A pair of macrochaetae on the hind margin of the first segment; two pairs on the second segment, one in the middle, the other on the hind margin; on the third segment a pair in the middle, and the usual row on the hind margin; two rows on the fourth segment. Legs, coxae and femora reddish; tibiae
reddish browa; tarsi brown. lubilli musually large; ungues? (The wings in the described specimen are injured.) Length. 7 mm ."
"A single specimen bred from Cynthia [Vanessa] carlui (C. V. Riley). This species is like E. futilis in the tistribution of bristles on the front and in the structure of the antennae. It differs in the presence of an additional pair of macrochaetae in the middle of the sceond and of the thirl abdominal segments; also in the comparitive smallness of the intermediate pair of macrochactae on the apex of the scutellum."

In comparing the above description of Osten Sacken's with the type specimen, I find but one thing I would amend. Baron Osten Sacken describes the legs (femora and coarae) as "reddish." I would insert the word yellow after it. Whether this unusual light color is normal, and, if so, of rarietal or specific value, I cannot decide; but in a specimen sent by Mr. Scudder, and bred from Thanaos brizo, I can not find any other important differences, aside from the sexual ones of the fiontal bristles and pulvilli. The legs in this specimen are quite black, the tibiae only being a little reddish. Such distinct difference I have never seen in allied Tachinidae, but until further specimens are examined, it will be better to consider it varietal, and which may be indicated by the name proserpina. The front in both sexes is narrower than usual.

Exorista hirsuta Osten Sacken. Pl. 89, figs. 13-15.
Tachina (Exorista) hirsuta Osten Sacken, Canadian Entomologist, xix, p. 163, 1887.
Male.-Face and cheeks silvery gray, the sides and cheeks changing in different reflections, the ground-color black, with the oral margin in front yellow; above the vibrissal bristle there are two or three small bristles, and abore these there is a row of hairs, not reaching as high as the lowermost of the frontal bristles. Antennae black, reaching to near the oral margin; the third joint broad, with parallel sides, three or four times as long as the second joint; arista thickened for more than half of its length. Palpi dark brown or black. Front less thickly pollinose than the face, with a yellowish cast, the black ground-color more apparent above; median stripe broad, deep reddish brown. The single row of well-pronounced bristles descends below the base of the third antennal joint, there being three below the base of the antenuae; posteriorly the row terminates in a stont, long, vertical, backwardly directed bristle; the two bristles in the same row in front of these are only a little stronger than the more anterior ones. Just without the two vertical bristles there is, on each side, near the angle of the eye, a smaller bristle directed outward and backward behind the vertical margin; in the middle there are two small bristles directed gently forwards; in front of the ocelli the usual pair of stout, anteriorly and outwardly directed bristles. Eyes pubescent. The bluish black, shining mesonotum shows very distinctly through the grayish dust, which leaves (when seen from behind) flve stripes, the middle oue of which is very slender; the bristles of the mesonotum are rather stout. Scutellum red at the tip; on each side the margiu has three bristles, and at the tip there are two approximated, additional, weak ones. Abdomen black, witli a broad, grayish, pollinose band at the base of the second, third and fourth segments, variable in differeut reffections; first segment with a pair of bristles behind, second with a median and posterior pair; third with a median pair and the usnal posterior row; the bristly covering of the abdomen is, however, stronger and thicker than usual, so that these bristles are only moderately differentiated from the rest. Legs wholly black. Front femora pol. linose behind. Wings grayish hyaline; tegulae nearly white. Leugth, 7 mm .

Female.-Like the male, except that the third antennal joint is comparatively
shortcr and broader, the epistoma somewhat projecting, and the two usual, anteriorly directed, orbital bristles are present. The second abdominal segment has a pair of posterior bristles, as in the male.

Two specimens, the type, and a male from Mr. S. H. Scudder, both bred from Pieris rapae. Characteristic of the species is "on the fourth abdominal segment a number of macrochaetae, giving it a bristly appearance ; the smaller hairs of the abdomen are more erect, longer and bristlelike than in E. futilis and E. blanda," as stated by Osten Sacken. It is possible that this species may be the same as E. vulgaris Meigen, parasitic in Europe upon Pieris rapae. The description applies. In the type specimen the two bristles on the posterior margin of the second abdominal segment are wanting and so described by Osten Sacken, but a careful examination discloses their scars.

## Exorista theclarum Scudder. Pl. 89, figs. 17, 19.

Tachina theclarum Scadder, Canadian Entomologist, xix, 165, 1887.

#### Abstract

Male, femate. - Face silvery gray, but little variable in different reflections, the ground-color of the sides helow, and the oral margin in front, red; there are but four or five short, bristly hairs on each side, above the vibrissal bristle. Palpi black. Antennae black, reaching to the oral margin, the third joint rather broad, of equal width throughout, and four or five times as long as the second joint. Sides of the front more thinly gray pollinose, the shining blue-black ground-color easily apparent above; medial stripe moderately broad, reddish brown, acutely emarginate behind for the shining ocellar space; bristles arranged as in E. hirsuta, the uppermost two bristles of each lateral row jnst below the ocelli are stout and much stronger than the ones preceding them ; below, the bristles descend on the side of the face as in E. hirsuta; among the frontal bristles are erect, fine black bairs; in the male, the bristle at the npper angle of the eyes and the orbital frontal bristles are wanting. Mesonotum shining blue-black, not thickly pollinose; when seen from bebind, with the beginning of five distinct, slender stripes. Scutellum broadly red on its border; the margin on each side with three stout bristles, and, at its apex, with a moderately approximate pair, scarcely smaller than the others. Abdomen shining; on the third and fourth segments nsually metallescent black; second segment with a broad, basal, pale gray, pollinose band, variable in different reflections; often a similar, narrower one on the third segment; anterior angles of the thirl segment in the male with a red spot; first and second segments each with a posterior pair of bristles, strongly differentiated from the erect, bristly hairs of the dorsum. Legs black. Wings grayish hyaline; tegnlae white. Length, 5 mm .

Seven specimens, including the types; three bred from Cyaniris pseudargiolus, the fourth from the District of Columbia (Pergande), the fifth without locality (Connecticut?), and the types, bred by Mr. Saunders from Thecla calanus. The metallescent color, usually apparent on the posterior part of the abdomen, together with the small size, will help to render this species recognizable. Mr. Scudder's description, drawn from living specimens, speaks of the abdomen as "piceous," and it may be well to note that in many specimens the abdomen acquires a deeper opacity, with more obscurity of the lighter ground-color after death.

Exorista scudderi, n. sp. Pl. 89, fig. 20.

Male.-Face in ground-color yellow, with silvery white, variable sheen; the cheeks, except the narrow orbital margin are blue black, and but thinly dusted; there are but three or four small bristly hairs above the vibrissal bristle. Palpi reddish yellow. Antennae black, the third joint largely red at the base on the moder side; third joint not broad, of equal width, truncate at the tip, scarcely twice the length of the rather long second joint. Front narrowed above, the sides in ground color black, with grarish or slightly yellowish pollen ; median stripe broad, nearly twice as broad as the sides, in color reddish brown; the single row of bristles on each sicle of the front reaches to nearly opposite the base of the third antemal joint, the bristles themselves are thiv and slender, scarcely differentiated in size from the vertical ones; the vertical bristles are arranged as in E. hirsuta, that is, with three pairs on the margin and one pair in front of the ocelli. The shining black ground color of the mesonotmen leaves four broad and distinct gray pollinose stripes. Scutellum wholly black, thinly pollinose ; its margin on each side with three bristles, and its apex with two small approximate ones. Abdomen black, the second and third segments apparently with variable pollinose bands; flrst segment with a posterior pair of bristles; second segment with a median and a posterior pair; third with a median pair and a posterior row ; bristly hairs of abdomen rather long and erect aud not strongly differentiated from the above mentioned bristles and those on the distal segments; the sicles of the second and third segments broadly, the fourth seg. ment wholly, yellowish red or reddish yellow. Veuter reddish yellow, with a narrow median blackish stripe. Legs black. Wings grayish hyaline. Length, 6 mm .

One specimen, Texas (Belfrage), reared from Theela autolycus, May 15.

$$
\text { Phorocera edwardsii, n. sp. Pl. 89, fig. } 52 .
$$

Female.-Face opaque white, scarcely at all variable; the cheeks below the eyes, only, show indications of the ground color. The lateral rows of bristles on the sides of the median depression are well-developed, ant reach nearly or quite to the base of the third antemnal joint and to opposite the last bristle of the frontal rows. Antennae black, the second joint reddish yellow; third joint reaching nearly to the epistoma, of equal width throughont, not narrow. Palpi reddish yellow. Sides of the front with a distinct brassy yellow tinge, broader than the median reddish brown stripe; near the orbit on each side there are two bristles directed anteriorly, and on the vertical margin there are two pairs situated near the upper angle of the eye; the onter one, the smaller of the two, is directed obliquely outward and backward, the inner one backward; behind the middle of the vertical margin there is an obsolete approximated pair of short bair-like bristles; the usual pair of anteriorly directed bristles in front of the ocelli is present. Mesonotum rather strongly gray pollinose, leaving four distinct broad, more shining stripes. Scutellum broadly reddish, its margin on each side with three stout bristles, its apex with a pair of small ones. Abdomen shining black; the second, third and fourth segments each with a broad, distinct, gray, basal band, variable in different reflections; first and sccond segments each with a pair of stout posterior bristles, second and third segments withont median pair; the corering of the abdomen, aside from the bristles mentioned and those on the last segment, is composed of short decumbent bristles, strongly differentiated from the others. Legs wholly black; front femora gray pollinose behind. Wings grayish hyaline; tegulae white. Length, 7 mm .
[The following description of the puparinm was taken during llfe:-Depressed cylindrical, rather short and thick, a little larger at the posterior end where there is a raised, prominent tubercle having at each lateral corner a prominent wart; on each side is a double row of impressed and sunken nearly continuous longitudinal furrows; the
surfacc is rough with transverse wrinkles and the color uniform dead black. Length, 8.25 mm . ; leight, 4.25 mm . ; breadth anteriorly, 3.5 mm . ; breadth posteriorly, 4.5 mm .; length of tubercles, .75 mm . s. H. s.]

Four specimens, bred from Euvanessa antiopa L. (G. Dimmock, L. 577), Anaea andria (C. V. Riley), and Chlorippe celtis (C. V. Riley, No. 48302 , Oct. 9, '82.). The European parasite of this species, P. concinnata Meig., seems to be different. This species is respectfully dedicated to Mr. W. H. Edwards, the well known lepidopterist.

## Phorocera saundersii, n. sp.

Female.-Front and face black only thinly whitish dusted. Frontal stripe broad, black. Arrangement of bristles normal; the frontal rows descend further on the face than usual. and turn ontwardly nearly to the eyes, the bristles strong, and the four npper ones of the row directed backward. Antennae black, the third joint reaching nearly to the oral margin; arista thickened to near its end. Palpi reddish at the tip. Mesonotum shining metallescent bluish black, imperfectly concealed beneath the thin pollen. Distal balf of the scutellum red; the median pair of marginal bristles approximate and small. Abdomen shining, metallescent black, thinly pollinose in an oblique light; first segment with a pair of bristles on the hind margin; secoud segment with three pairs of bristles, one pair near the front margin, another near the middle, and the third behind; third segment with two pairs, corresponding to the first two pairs of the second segment, and with the usual row behind; the bristles are well differentiated from the general covering of the abdomen, and towards the tip give a rather strongly hirsute appearance. Legs black. Wings grayish hyaline; last section of the fourth vein strongly coucave after the angle. Length, 9 mm .

One specimen (Dr. Riley's collection), bred from chrysalis of Argynnis cybele.

## Phorocera comstocki, n. sp.

Female.-Front broad and convex, silvery gray pollinose ou the sides; the median stripe distinctly less than one-third of the width ; arrangement of bristles normal, the bristles themselves not very stout. Face in ground-color reddish-yellow, densely grayish white, pollinose; the moderately stont bristles of the edges of the facial depression reach vearly to a point opposite the lowest one of the frontal row, and below the base of the third joint of the antennae. First two joints, and base of the third of the antennae, reddish yellow, third joint not broad, four or five times as long as the second; arista thickened on less than half its length. Palpi yellow. Mesonotum densely pollinose, leaving two slender, posteriorly abbreviated stripes, and an outer, abbreviated and interrupted stripe on each side. Scutellum yellow on distal part. Abdomen elongateconical, densely and broadly fasciate with gray; first segment without (apparently) a posterior pair of bristles; second segment with two pairs, towards the front and behind; third with an anterior pair, and the usual row behind. Legs black; last section of the fourth longitudinal rein more oblique than usual, and not curved. Length, 9 mm .

Two specimens, male and female (of Dr. Riley's collection), bred from Megathymus yuccac. The front of the male is broad, and the claws and pulvilli are not enlarged.

Masicera archippivora Riley. Pl. 89, fig. 18.
Tuchina archippivora Riley, 3d Rep. Ins. Missouri, 150 (1871).
Female.-Face opaque gray; a row of moderate-sized bristles on the margin of the central depression, reaching two-thirds or more of the distance to the base of the antennae. Sicles of the front opaque yellowish-gray, the ground color scarcely visible; the median posteriorly bifurcated, dark reddish-brown stripe, narrower than the sides. Bristles of the front normal, that is, arranged as in Exorista futilis, hirsuta, etc. Palpi yellow. Eyes bare. Antennae black, the basal half of the third joint, aud more or less of the second, red or reddish; third joint from flve to six times the length of the second; arista thickened for half of its lengtlo or more. Dorsum of thorax rather densely gray pollinose, with a yellowish cast, leaving four black stripes, the median two of which are slender, and abbreviated posteriorly. Scutellum gray pollinose, the tip yellowish red; bristles normal (three ou each lateral margin, an apical pair, and a dorsal pair), stout, the apical pair approximated and small. Abdomen black, short, thickly gray pollinose, variable in different reflections; second segment with a posterior pair of bristles, no median bristles on this and the next segment; the general covering of short bristles well differentiated from the long bristles. Legs black. Wings grayish byaline; tegulae white. Length, $5-6 \mathrm{~mm}$.

Three specimens, bred from larvae of Anosia plexippus (Dr. Dimmock, L. 505). A male specimen, from Dr. Riley, bearing the label: "From larvae of Papilio, Greeley, Colo., July 31, '77," I cannot distinguish in the absence of other male specimens. The third antennal joint is more elongate and wholly black, and the pulvilli are not elongate.
[Dr. Dimmock's specimens came out of the nearly full grown larva of Anosia on July 20, pupated July 23, and the imagos appeared August 2-3.]

The above description is based upon specimens in a good state of preservation, but I am not at all sure that they are the same as the type of the species. Five specimens from Professor Riley, apparently including the originally described specimens, present certain differences that at first led me to deem them distinct. In most, the frontal stripe is narrow, as in the described specimens, but, in one ( 9 ) it is distinctly broader than the sides of the front; the third antennal joint, furthermore, seems more rounded upon the posterior inferior angle, giving it a more pointed appearance. In all these specimens the side of the abdomen is more or less red. In size they vary not a little, some being distinctly larger, others distinctly smaller than the ones described. I suspect that they all pertain to one species, but further and careful observation is needed to remove the doubt.

Masicera frenchii, n. sp. Pl. 89, fig. 23.
Male, female.-Closely allied to M. archippivora, but distinguishable at once by the
elongate pulvilli of the male. The antennae are broader, and wholly black; the frontal
stripe is fully as broad as, or broader than, the sides. The facial depression is broader,
and the color of both face and front more distinctly yellow. The grayish pollinose
stripes on the shining blue-black mesonotum are less dense, as is also the grayish
covering of the abdomen. The abdomen has no red on its sides. Lengtb, 6.7 mm .
Five specimens, bred from Jasoniades glaucus, November 26, 1881. Moosehead Lake, Me. (S. H. Scudder).

## Masicera rileyi, n. sp. Pl. 89, figs. 22, 24.

Male.-Front on the sides distinctly yellowish pollinose; the deep red median stripe a full third of the width of the front; the small bristle near the angle of the eye, and the small, median, vertical pair present, in addition to the usual stout, vertical, posteriorly directed, and the less stout, similarly directed pair on the upper part of the front; the lateral rows are composed of numerons, not very stout bristles, and reach to the base of the third antemmal joint. The ground-color of the cheeks and face is chiefly yellow, partly concealed beneath the changeable polleu; the small bristles on the sides of the depression reach nearly to the middle. First two joints of the antennae yellow, the third black, rather narrow, and scarcely three times as long as the second. Palpi yellow. Mesonotum thinly pollinose, the usual stripes apparent from bebind. Scutellum, except the narrow base and lateral margin, reddish yellow; the apical pair of bristles very small and approximate. Abdomen yellowish red, with a broad median stripe, and the hind margins of the posterior segments black; the abdomen is clothed rather thickly with recnmbent, bristly hairs, and the bristles, which are confined to the hind margin of the third and the fonrtb segment, are not large or conspicuous. Legs pitchy black; claws and pulvilli small. Wings as usual. Length, $7-8 \mathrm{~mm}$.

Three males and four females from Dr. Riley, labelled: " 153 , parasitic on [Heraclides] cresphontes," and " 358 , Feb. 24, ' 80. ." The female shows but little difference from the male, aside from the lateral orbital bristles; the third antennal joint appears to be a little broader.

## Masicera (Phorocera?) sp.

A single male specimen, from Professor Riley, bearing the label: "June 23, '\%9, par. on antiopa," I am not quite sure whether to locate under Masicera or Phorocera. The under portion of the eye is very sparsely hairy, almost doubtfully so, but the absence of median bristles on the abdominal segments indicates a closer relationship to Masicera. The front and face are yellowish pollinose, the frontal stripe a third of the width of the rather narrow front. Antennae black; palpi yellow. Leg black, somewhat pitchy; claws and pulvilli elongate and large. From M. rileyi, the narrower front, more black abdomen, and especially the elongate claws and pulvilli will distinguish it. To M. frenchii, the relationship is closer, but the third joint of the antennae is shorter (in frenchii the third joint is four or more times as long as the second), and the abdomen is not wholly black. From the species of Phorocera bere described, the entire absence of bristles on the second segment of the abdomen will distinguish it. Should the characters above given serve to fix the species, it may be called M. dubia.

## ADDITIONS AND CORRECTIONS.*

Page 11, note. The statement here regarding Pamphila mandan is inaccurate (see correction p. 1565). For Coolidge, read Chapman.
14, 16. The licad lines should read Bntterflies.
14, line 19 , for montivagus, read montivaga.
15. For Thestor (twice) read Tomares.
16. For a fuller account of the structure and action of Curetis, see de Nicéville's Butterflies of India, iii : 7-8.

33, 35. In the bead lines, for caterpillar, read chrysalis.
47. Muscular system; lines 6 and 7 should read: and above, some to the bases... as a lever, but the mass to the upper wall, serving to flatten the thorax aud so raise the wings ; besides, etc.
71, lines 6 and 8. Mabille's name should certainly have been added to the French, and de Nicéville's to the English names.
72-75. A somewhat extraordinary disquisition, in opposition to the views here maintained, views which seem to be very poorly apprehended by the writer, will be found in the Can. ent., xxi, nos. 4, 5 (1889).

84, line 13, for contracted, read contrasted.
107, line 17. For medium, read median.
114, last lines but 2 and 8. For larger, read longer.
117. Characteristics of the Satyrinae. Notes on the transformation of the members of this subfamily are given by Edwards, Can. ent., xxi : 63-68 (1889).
120, line 22. I have later, Excursus XL, mentioned some odoriferous Satyrinae, and de Niceville tells me they are not uncommon in India and the odor is always fragrant.
149. Oeneis jutta. Further notes on the history of this species are given by Fyles, Can. ent., xxi: $12-13$ (1889).
152, line 28. For Gideon, read Gamble.
153, line 20. I learn that jutta was discovered by Prof. C. II. Fernald at the OronoStillwater bog, in 1879, before Mr. Braun came to Bangor.
155, line 8. Juniper is a local name in Maine and the maritime provinces for the American larch, Larix americana.
165, line 14. The comma should be a semicolon.
168, line 5. For Stenacke, read Stewiacke.
180. Enodia portlandia. An interesting account and abundant illustrations of this insect in all its stages will be found in Edwards's Butterflies of N. A., iii, part v.

193, flrst column of synonymy, line 15 , for Neonymaha, read Neonympha.
203. Neonympha phocion. This butterfly is described in all its stages by Edwards, with his customary wealth of illustration, in the Butterflies of North America, 3d series, part vi, Dec. 1888.
209. The head line shonld read : The genus Cissia.
231. The head line should read: The genus Chlorippe.
247. Parasites. Pimpla annulipes should probably be added; see p. 1885.

248, first and last lines, for ovata Say, read flavipes Fabr.
273, line 1, for caudicans, read candicans.
Line 17, for say, read says.
274, line 22, for were, read was; for their, read these.
285, line 15, for , read Vaccinium.

* Evident trpographical errors are not noted.

296. Hybrids. B. Arthechippus. Dr. Hagen assures me that Edwards's description and mine were based upon the same individual.

315, line 6, for erect on, read on erect.
326, lines 43,44 , the quotation should end with the word numerous.
327. Oviposition. Mr. Edwards tells me that Mrs. Peart observed one case in which the final egg of a chain had eleven ribs, when all the others had nine. Could a sccond female have possibly placed an egg upon a clain laid by another!?
338, line 5. Mr. Edwards assures me that there is no doubt that the specimen came from Mckenzie River.

Food plants. Mr. Edwards has seen a female lay an egr on a gooseberry bush, and obtained the egg.

377, line 16. For Doxocopa, read Chlorippe.
Last lines. For further notes on butterflies at sea, see Entom., xxi: 161-162, June, 1888.

379, Eugonia j-album. Add to the synonymy: Eugonia j-album Scndd., Foss. butt., 43,44 , pl. 1, fig. 4 (1875).
392, line 32, and 394, lines 6, 12, for Inachis, read Hamadryas.
394. Euvanessa antiopa. For further brief notes on the sound produced by this butterfly, see Insect life, i:221.
403. Food plants. Grove (Journ. N. Y. micr. soc., Oct. 1887) says he has found the caterpillar on the ailanthus tree, the castor bean and geranium! but his description of a colony on a castor bean leaf makes one think he has mistaken some other catcrpillar for that of E. antiopa.
406. Life history. Antiopa is reported by Jenner Weir as having been seen in flight on a warm December day by llaydon at Moose Factory, llndson Bay ! (Eatom., xv:115).
407. Hibernation. Grove found a colony of "at least fifty" under a foot bridge over a small creek in December, hanging by their feet; when breathed upon they showed sigus of life.

410, line 27, for 1nachis, read Ilamadryas.
419, lines 11, 18, for lnachis read llamadryas.
437, line 21, for Inachis read Hamadryas.
441, in the synonymy, for Papilo amiralis, read Papilio amiralis.
455. Parasites. Pteromalns puparum is to be added to the list that attack Vanessa atalanta in this country, and from the chrysalids of Eulophus referred to were only reared a secondary parasite, Cirrospilus niger. To the European parasites should be added Pimpla flavicans Fabr., according to Rondani.

476, line 22, for formed, read found.
477. Aberrations. Another instance of Vanessa cardui elymi, the fore wings very like the specimen in the llarris collection, but the hind wings also suffused, is described and figured by Clarkj(Entom., xiii :73-7t).

479, last paragraph. De Nicéville writes me that V. cardui is by no meaus confined to the mountains, but is to be found almost everywhere in India, thongh very rare in Calcutta.
481. Food plants. Riley writes that "a correspondent, Mr. J. G. Barlow of Cadet, Mo., has found larvac of cardui feeding abundantly upon Malva sylvestris," and he adds: "A species of what I believe is a Malva, though I have not had it determined, is a common food plant of the species along the New Jersey Coast, and it feeds here in Washington on Chrysauthemum and Flelianthus."
486. Enemies. To the European parasites, must be added, on Rondani's authority, Ichneumon castigator Fabr.

492, line 26, for 11 . charitonia, read A. charithonia.
493, line 21, for it takes, read they take.
496 , line 13 from bottom should end iu a colon, "this" having the sense of "the following."

518, line 15 from bottom, for born, read borne.

570, line 16, for do, read does.
572, line 12 from bottom, the $\delta$ sign should precede discernible.
614, line 7 from bottom (and in several other places), for Scoharie read Schoharie.
697, line 5, for Virburuum, read Viburnum.
717. line 26 , for mimicry, read examples of mimicry.
740. Life history. Although, as recorded ou p. 737, A. plexippus was exceedingly abundant in the northern half of New Fngland in the autumu of 1888 , and the winter of $18 \times 8-1889$ was mprecedentedly mild, with an exceptionally early spring, no butterflies had been observed, so far as I can learn, up to May 30 (the present writing), when one was hearl of; all of which accords perfectly with the account of the life history given in the text.

753, line 15 from bottom, the comma should come after surface.
758 , lines $7-8$. Thais, and therefore in the highest probability Thaites, does not belong, as I thought on insutficient examination, to the Parnassidi but to the Papilionidi. The egg is precisely as in the swallow tails, and the division of the segments of the caterpillar as well.

770, second paragraph. The chitinons anmuli of the first stage of the caterpillars of the Lycaenidae cannot be said to be nnique, for the crateriform annnli of the Hesperidae must be regarded as homologous structures.
776. The early stages of the Lemoniinae. When I wrote this section, and incleed until some time after its publication, I lad never seen Sepp's Papillons de Surinam, by the later obtaining of which I am obliged to make some modifications. Thus, Sepp asserts that the caterpillar and chrysalis referred by Stoll' to Euselasia crotopus do not belong here, but to the immediate neighborhood of the one whose transformations he figures as Papilio mammeae, and which is catalogued by Kirby under Nymphidium, thus transferring the insect from the Nemeobiidi to the Lemonidi. This, considering the other mistakes made by Stoll', and the confident expressions of Sepp, we could easily believe; only it is a little curions that Sepp says of his insect that the caterpillar is processionary, which Bar also asserts of Euselasia gelon; it is of course in no way inmossible that sucli a feature should ocenr botlo in Euselasia aud Nymphiclimm, but taken in connection with the evident error of either Stoll or Sepp, it is not a little strange, and some verification of the observations is evidently re'1uired; our present knowledge of the early stages of the family will hardly permit us to judge which was in error.

Sepp figures no less than six species of Lemoninae with their early stages, and oddly enough, considering the few that are given by Stoll', two of Stoll's species are repeated by him, which emables me to make some rectifications. One of these is in Nelicopis cupido (see p. 779) ; here I have evidently made the mistake of taking for the cast-off larval skiu what Stoll had intended for the front view of the larva, looking out of one end of its nest in a rolled up leaf. Stoll's representation is very poor, but the point brought out regarding the size of the head is the same, and is warranted by Sepp's far better fignre; here, too, is evidently the better source of the statement I thought without warrant, that the caterpillar constructed a nest much after the manner of the leaf rollers, which Sepp's figure distinctly slows, and which he also distinctly states, adding that it is more closely rolled, and the open end closed when the caterpillar is abont to change to chrysalis.

The other butterfy whose transformations are given by both authors is Stalachtis calliope, which Sepp tells us lays eggs in a mass, the caterpillars remaining in compauy until they change. The figure represents the caterpillar as having the same proportions as Stolls, but the head a little larger, and the same slicid on the anterior and posterior segments of the body; but what I had taken for black points on the intermediate segments are now shown, in the light of Sepp's figure, to be not mediodorsal, but laterodorsal or supralateral, and to be merely the bases of the series of supposed fascicled hairs; these, however, in Sepp's tigures, certainly do not represent fascicled hairs, but what are apparently long and tapering spiniferons filaments. As to the chrysalis, Stoll' and Sepp are again opposed; the chrysalis given by Sepp, thongh closely resem-
bling Stoll's in the markings, is far stouter and more regularly ovate, bnt like it shows a dorsal surface and no head. The accomnt of its position by Stoll is given on p. 781; Sepp gives a very different one: the caterpillar attaches itself by the abdomen to a branch, or often a leaf, and after having spun another band around its body changes to a chrysalis.
The four remaining butterflies given by Sepp alone, belong, like the last, to the Lemoniidi.

The first is Mesene nigrocinctus. The caterpillar is more distinctly onisciform than any other Lemonifd, no sign of the heal appearing in the figure, so that it is difficult, if not impossible, to dirine which is the head end; it is much less than twice as long as broad, oval, but more pointed at one end, apparently the head end, than the other, and seems to be tectiform, the mediodorsal line ridged, and miformly and sparsely covered with stiff, erect, tapering bristles, as long as the width of the body. Little can be said of the chrysalis as the details are poorly given, but it is of about the same size and proportions as the caterpillar, the tail more pointed than the head, and covered with similar bnt rather more delicate bristles, with no sign of fasciation. Sepp distinctly says it is girt abont the middle.

The next is Metacharis erythromelas. This has much the general form of an ordinary Lycaenid larva, but has the front portion a little swollen, somewhat like an Amblypodia, and is slender posteriorly, the whole creature fully three times as long as its greatest width; the head does not appear distinctivcly as such, and is apparently, at least in part, retractile within the swollen mass behind it, and, moreover, this is furtherindicated by Sepp's expression that "in walking, the caterpillar advances its heal." The sides of the body along the infrastigmatal fold are furuished with little triangular, fleshy processes, concealing the legs; the whole body is sparsely clothed with long, delicate, gently curving, erect, and apparently delicate hairs, with no sign of fasciation or special distribution; besides, says Sepp, they are covered with a white powder, which spreads also on the leaves where they crawl, but which is less apparent as the caterpillar grows larger. The chrysalis, which is rather obscurely drawn, partly on account of the white powder which appears still to cling to it, is not very unlike a Lycaenid chrysalis, but tapers more in a conical form on the abdomen, like the Lemoniinae generally; it is a little more than twice as loug as broad, without prominences, bluntly rom ded at the front, which apparently terminates with the prothorax, covered with large spots and with a few long bristles, not so long as those of the caterpillar. It is girt around the middle.

The third is Nymphidium mammeae, already referred to. Here the caterpillar wholly resembles in general appearance, with only speciflc differences, the caterpillar attributed by Stoll' to Euselasia crotopus, with its two erect, stiff filaments behind the head, "points très élevés," Sepp calls them; it is considerably slenderer, however, than Stoll' represents it. The chrysalis is also similar in shape in every respect, though of very different and livelier colors. Sepp adds that the eggs are laid in a mass and the caterpillars live in company, and are processionary, eating little and growing slowly. The chrysalis is so tightly girt around the middle as to prevent all movement.

The last iustance is an allied insect called Papilio caricae by Sepp, clearly of a different genus, but placed by Kirby in Nymphidium, as by Bates before him. The caterpillar has the same form as the last, is a little less than three times as long as broad, but has no erect bristles behind the head; the head, however, has a rounded, vertical prominence on either side and has a radiating frill of aculiform bristles as long as the head, encircling the hinder face; a few short hairs are seen at the extremity of the body which otherwise is apparently naked, An interesting point in its natural history is that it lives on the upper side of leaves exposed, and is always surrounded by very small ants; this being the only instance known to occur, so far as I am aware, among the Lemoninae. The chrysalis is hesperidiform, a little more thau three times as long as broad, the bluntly rounded front apparently terminated by the prothorax, and a subconical, pointed abdomen; it is girt around the middle.

Sepp is careful to give the food plants of his insects, by which it appears that there
is as much range among the Lemoniidi as among the Nemeobiidi. Thus Nymphidium caricae feeds on Inga vera, one of the Legominosae, the same family which nourishes Lemonias; Nymphidium mammeae on the Manay apple, Mammea amcricana, one of the Guttiferae; Mesene nigrocinctus on Pauliuia pinnata, one of the Sapindaceae; Stalachtis calliope, whose food is not given by Stoll', on the Sappodilla, of the Sapotaceae; and Metacharis erythromelas on Phoradendron trinervium, one of the Loranthacear.

These additional data show that the concinsions stated on p. 783 regarding the possible distinction between the Nemeobiidi and Lemonidi in their early stages are not wholly warranted. In the first place it becomes necessary, until verification, to throw out of consideration the two species of Euselasia and the two of Nymphidium until their accuracy is garanteed by new experiments ; and again there is no sign of any fasciation in the clothing of the caterpillar of Mesene and Metacharis, and not only are the chrysalids of both these species girt, but, according to Sepp and contrary to Stoll' and Bates, the same is true of Stalachtis.

On the other hand these additional instances of known transformations strengthen the position assumed that the transformations and early stages of the Lemoninae do not cliffer sufficiently from those of the Lycneninae to warrant the separation of the two groups as distinct families.

776, note. Sepp figures a rery similar but certainly not identical caterpillar (witness the length of the fleshy fllaments) as that of Mechanitis polymnia.

777, line 25, for it, read the latter.
787, line Il. It was Sara Coleridge. She wrote: "Butterflies are better flies-larger flies, the largest sort of flies that you meet with." See her Memoir' and Letters.

792 , line 3 , real male.
Line 42 , for not all, read not at all.
793. General characteristics. De Nicéville (Butt. India, iii: 5) gives tables of the genera of Indian butterflies in which he has detected secondary sexual distinctions in the form of patches of special scales or tufts of hairs, on the fore or hind wing or both, in which twenty of the thirty-two genera of his work are included, and an excel$l_{\text {ent }}$ account is there given of the habits of the family. De Nicéville also gires, p. 11, a list of a considerable number of mimicking and protected genera of Indian Lycaeninae, prepared by Doherty.
796. Attendance of ants on caterpillars. A most extraordinary account is given by Mrs. Wylly of the action of ants in herding Lycaenid larvae (Journ, Bomb. nat. hist. soc., iii : $166-167,1888$ ), which gives force to Thwaites's observations. Sepp also states that the larva of one of the Theclidi of Surinam is attended by ants, as well as of one of the Lemoniidae, both of which statements have never been verified or repeated with any other members of their respective groups, so far as I am aware, and inclicate how mach we have to learn.
797. De Nicéville brings together (Butt. India, iii : 9) several instances of chrysalids of Lycaeninae attached by the tail ouly, and either so firmly attached as to be held rigidly in a horizontal position, or, as in Poritia, Spalgis and Tajuria, hanging freely, and he thinks the exceptions to the ordinary position and girding "many." But two of his instances are based wholly upon the illustrations of Moore who also figures one of the Pierinae in a similar, evidently false, position, and, therefore, little dependence is to be placed upon them. I do not mean to deny the occurrence of free hanging chrysalids among the Lycaeninae, but I think each supposed instance needs to be rerified by additional observation ; one instance, which may be accidental, is not enongh, for if the girth is accidentally broken, the chrysalis, in most instances, would naturally fall and hang by the tail.
813. I failed to note that I had taken S. titus in the American Fork Canon, Utah. 825, line 24 , read not further raised.
833. Life history. Mr. Fletcher obtained two eggs of I. niphon on May 16th, laid on the Joung shoot of white pine, just pushing forth. I am inclined to think that it is just here that all eggs are laid on Coniferae by butterflies.

848, line 26, read not further raised.
868, second line of poetical quotation, for Eit, read Lit.
881, line 3, for where the, read where they.
882, second paragraph. Dr. Fitcli obsersed this caterpillar attacking plums, as long ago as 1870 , as appears from the following passages found among his notes:-
"June 5, 1870. Noticed a foung Smith's Orleans plum, now grown to over a half inch in length, haviug a conical hole eaten in its side, passing deep in, through the centre. First thought this the work of some bird; but looking further saw the next plum below eaten through and through till it was now nearly all consumed and this worm with its head sunk into the hollow remaining part of the plum, and its body clinging to the npper end of the fruit stem. Put the worm into a tumbler with a young wild plum and leaves.
"June 6,1870 , it has eaten a hole deep in the side of the plum on which it stands with its head sunk down into this hole, and has discharged a profusion of soft wet feces of a dull pale yellow color, some adhering to the side of the plum, but most of them fallen down to the bottom of the tumbler.
"June 10, it has now eaten out all the inside of the plum, making a hollow cavity in it, consuming about a third of the plum and has fastened itself to the paper covering the tumbler-fixing its hind end to the paper, and with several silk tbreads forming a loop to hold the fore part of its body up in contact with the paper-these threads commencing separately and spread apart at their ends, and drawn together and sunk into the suture between the thorax and abdomen. It has thus taken on its pupa form, held against the paper with its back downwards."

I add his descriptions of the early stages:-
" Larva 0.55 loug, 0.20 thick, regnlar oval or a little more narrowed at hind end, bluntly rounded at each end, sutures very distinct, marked by transverse constrictions, except the two last, which are less plain. Twelve segments, the anterior ones, after the head, shortest, and slightly increasing in length backward. No projecting processes. Surface closely bearded with short bairs. Color bright apple green. A faint pale green-ish-yellow dorsal line, bordered each side by a faint green stripe-this yellow line ending on the fourth segment from the tip, and these last segments have a deeper green clorsal stripe faintly bordered each side with pale greenish yellow. The back occupied on each side by oblique faint stripes of green and greenish yellow, alternating; the yellow stripes beginning a little back of each breathing pore, and embracing the pore, and passing diagonally forward and upward across the two segments next forward of the pore, to the green dorsal stripes bordering the dorsal line. Breathing pores very small, glossy, nankin yellow dots. Lower part of each side green, with a slender, pale yellow stripe. Underside and legs dull whitish.
"Pupa 0.35 long, and about 0.20 wide and 0.20 high, oval, broatest beyond the middle, the anterior third of its length slightly narrower than it is farther back; anterior eud bluntly rounded; hind end gradually tapered to a bluntly rounded tip. Abdominal segments distinctly marked by impressed transverse sutures. Head separated from the body by a similar transverse suture, its anterior side rounded, the line bounding it forming about a third part of a circle. Color dull yellowish brown, mottled with black, the whole surface bearded profusely with gray hairs, except on the flattened undersicle. The spiracles forming a row of white dots along each side; and in the suture at base of head, hear its onter end on each side is a short streak resembling white pruinous matter.
"July 1st found it hatched a Thecla butterfly, lying dead on bottom of tumbler." His description of the same enables me to determine it to be Thecla liparops.

907, line 35 , for continues, read continue.
960, line 29, for Astralagus, read Astragalus.
962, line 16-13 from bottom. As stated above in these additious, Sepp asserts that the caterpillar of "Thecla" ingae, and of Nymphidium caricae, the latter one of the Lemoniinae, are likewise attended by ants, and presumably for the same cause as the larvae of Lycaenidi.

Last line. See preceding note.

967, line 23, for Labache, real La llache.
1070, line 1f, for Terias, reud Eurema.
1071, line 25, for frost, read tirst.
1100, foot note, for Long, read Lang.
1122. Life history. Mr. Fletcher sends me the first specimen, a male, taken or seen by him at Ottawa in 1889, May 24, and it has much the appearance, as he remarks, of having hibernated.
1125. Enemies. The reference to Megorismus is unfortmate; the specific name is umpublished, and it is by accident that it was referred to E. philodice as a host. The clusters of cocoons referred to doubtless belonged to some Apanteles, of which Mesochorus was a hyperparasite.
1127, col. 1, line 4, read ednsa; col. 2, line 7, read eurytheme.
1136. Enemies. The asilid fly was afterwards determined by Riley as a species of Stenopogon.

1162, line 10 , for nsually, read umusually.
1210 , line 5 , for napa, reud rapa.
1224, lines 24,25 . This statement requires modification. Thais, at least, belongs to the Papilionidi; see, above, the correction for p. 758.

1261, in the line of Greek, omit the second comma.
1279, line 20, after anuulipes, insert (88:6).
1280, column I, nuder General, add: $88: 6$. Pimpla aunulipes, a parasite,
1344, line 24 , for humeralis, read utilis (88:4).
Under General in List of Illustrations, add: $88: 4$. Hemiteles utilis, a parasite.
1378. In the synonymy, for Gonuiurus, read Goniurus.

1394, line 5, read (41: 2).
1422, line 16, for Ipomaea reat Ipomoea.
1455, line 6, for Polygonia faunus, reat Polygonia comma.
1511. Food plants. Professor C. II. Fernald informs me that he reared this species in the spring of 1889 , from caterpillars feeding on choke cherry, Prnnus virginiana.

1529, line 23, for tessellata, reud montivaga.
1594, lines 17,18 . In writing this I overlooked observations of my own on Calpodes, made many years ago and recorded on pp. 1755-1756.
1648. Comparisons. In several places for P [amphila], read E [rynnis].

1715, line 9. The species here referred to as L. palatka, is not the palatka of Edwards, but his pallas. See p. 1864:

1794, 2 d column of synonymy, line 1 , read troglodyta.

## CORRECTIONS IN TIIE EXPLANATIONS OF PLATES.

3:12-13. These should be interchanged. 12 represents P. i. umbrosa; 13, P.i. fabricii.

49: 4. The scales in $b$ and $e$ are from the middle of the stigma itself.
63 : 7-8. These should be interchanged. 7 represents the ovary cells; 8 , the mesoderm cells.
74. The plate was printed in nineteen colors.
83. This plate was printed in twenty-two colors.

88:4. Should read Hemiteles ntilis.

## DATES OF PUBLICATION.

This work was originally issued in twelve parts, which were published as follows :-
Part I, containing pages 1-40, 105-208, plates $1,14,18,46,52,67,70$ and the Physical map, November 1, 1888.

Part II, containing pages 41-88, 209-304, plates 2, 19, 38, 43, 62, 78, 83 and the Faunal map, December 1, 1888.

Part III, containing pages $305-448$, plates $11,20,33,39,53,71,74$ and the map of the Wbite Monntains, January 1, 1889.

Part IV, containing pages 449-592, and plates 3, 16, 21, 22, 34, 54, 64 and 79, February $1,1889$.
Pait V, containing pages $593-736$, plates $4,23,40,55,61,68,75$ and the portrait of Abbot, March 1, 1889.
Part VI, containing pages $737-880$, and plates $5,12,24,25,35,44,72$ and 81 , April 1 , 1889.

Part VII, containing pages $881-1048$, plates $6,26,27,41,47,56,82$ and the portrait of LeConte, May 1, 1889.
Part V111, containing pages $89-104,1049-1216$, plates $7,13,28,45,57,65,73$ and the map of the distribntion of Pieris rapae, June 1, 1889.

Part IX, containing pages $1217-1400$, plates $8,29,36,48,58,69,77$ and the portrait of Harris, Jnly 1, 1889.

Part X, containing pages 1401-1552, and plates $15,17,30,49,59,66,85$ and 87, August 1, 1889.
Part XI, containing pages 1553-1774, and plates $9,31,37,45,50,76,80$ and 88 , September, 1, 1889.

Part XIl, containing pages i-xxiv of Vol. I, i-xii of Vol. I1, i-viii of Vol. III, pp. 1775-1958, and plates $10,32,42,51,60,84,86$ and 89 , October 1, 1889.

## INDEX.

## LIST OF SUBSCRIBERS, MAY, 1889.

Eugene M. Aaron, Esq., Philadelphia, Pemn. Acadeyy of Natural Sciences, Philadelphia, Penn.
Dr. A. Agassiz, Cambridge.
American Academy of Arts and Sciences, Boston.
Amierst College Library, Amherst. James Anges, Esq., New York.
Dr. Alexander Grailam Bell, Washington, D. C.
Rev. Cifarles J. S. Bethune, Port Hope, Can.
Miss Caroline HL. Blatcuford, Cambridge. Boston Atheneum.
Boston Public Library.
Boston Society of Natural History.
William Brewster, Esq., Cambridge.
Martin Brimier, Esq., Boston.
Brown Unitersity Library, Providence, R. I.

Prof. Lawrence Bruner, Limcoln, Neb. Dr. William S. Bryant, Boston.
Mrs. Edward Buck, Andover.
Edward Burgess, Esq., Boston.
Prof. Edwin E. Calder, Providence, R. I.
Dr. Arthur P. Chadbourne, Cambridge.
Dr. Chapman, Hereford, Engl.
W. B. Clarke \& Co., Boston.

Prof. E. W. Clarpole, Akron, O.
College of New Jersey, Princeton.
Corsell University Library, Ithaca, N. Y.
Department of Agriculture, Washington.
if L. Distant, Esq., London, Eugl.
Mirs. Hemry Draper, New York.
Delau \& Co., London, Engl. (Three copies.)
W. H. Edwards, Esq., Coalburgh, W. Va.

Miss ida M. Eliot, New Bedford.
S. A. Elurs, Esq., Rochester, N. Y.

Capt. H. J. Elwes, Preston, Engl.
Extonological Society of Ontario, London, Can.
Joseph Story Fat, Esq, Boston.

Fellowes Atheneem, Roxbury.
Prof. C. H. Fernald, Amberst.
James Fletcher, Esq., Ottawa, Can.
Free Public Library, New Bedford.
Free Public Library, Worcester.
Prof. G. H. French, Carbondale, Ill.
R. Friedlander \& Sohn, Berlin, Germany. (Two eopies.)
Thomas Gaffield, Esq., Boston.
Gerold \& Comp., Vienna, Austria.
Mrs. T. K. Gibbs, New York.
F. D. Godman, Esq., Loudou, Engl.

Yrof. George L. Goodale, Cambridge.
George Warren Hammond, Esq., Boston.
Herr Otto Harrassowitz, Leipsic, Germany. (Five eopies.)
Edward Doubleday Harris, Esq., New York.
Rev. W. J. Holland, Ph.D., Pittsburgh, Pem.
C. Eustis Hebbard, Esq., Cambridge.

Gardiner G. Hubbard, Esq., Washington, D. C.

Dr. Alexander IIutchins, Brooklyn, N.Y.
Illinois State Laboratory of Natural Ifistory, Champaign.
Indiana University, Bloomington.
Dr. George G. Kennedr, Roxbury.
W. F. Kirby, Esq., South Keusington, Engl.
R. D. Lacoe, Esq., Pittston, Penn.

Library of Congress, Washington.
J. A. Livtner, Esq., Albany, N. Y.

Little, Bromn, \& Co., Boston.
Mrs. Join Lomell, Chestnut Hill.
Prof. Оtтo Lugger, St. Anthony Park, Minn.
II. H. Lrman, Esq.. Montreal, Can.

McGill College, Montreal, Can.
H. G. Marqtand, Esq., New York.
W. Potrell Mason, Esq.. Boston.
S. A. Maxifell \& Co., Chieago, Ill.

Prof. Alpred M. Mayer, South Orange, N. J.

Miss A. L. Mayo, Boston.
Mercantile Library, New York.
Prof. L. C. Miall, Yorkshire College, Leeds, Engl.
William Minot, Jr., Esq., Boston.
Miss Emily L. Morton, Newburgh, N. Y.
New Britain Institute, New Britain, Conn.
Lionel de Nicérilie, Esq., Calcutta.
M. Cearles Obertiür, Rennes, France.

Alfred Pell, Esq., Highland Falls, N. Y.
Mr. R. H. Porter, London, Engl. (Three copies.)
Providence Athenecm, Providence, R. I.
Public Litbrary, Toronto.
Mr. Bernard Quaritch, London, Engl.
Prof. Robert If. Richards, Jamaica Plain.
Dr. C. V. Riley, Washington, D. C.
M. D. Ross, Esq., Jamaica Plain.

Rutgers College Library, New Brunswick, N. J.
Horace E. Scudder, Esq, Cambridge.
Miss J. M. Scudder, Brookline.
J. Montgomery Sears, Esq., Boston.

William Sellers, Esq., Philadelphia, Penn.
Baron de Sélys Longchamps, Sénatcur, Liége, Belginm.
Mr. Charles W. Seter, Cambridge.
Silas Bronson Library, Waterbury, Comn.
F. B. Smpson, Esq., New York.

Ellison A. Smyti, Esq., Charleston, S. C.
Prof. F. H. Snow, University of Kansas, Lawrence.

Prof. J. Y. Stanton, Bates College, Lemiston, Me.
State Normal. School, Framingham.
Dr. O. Staudinger, Blasewitz, Germany.
Swedish Academy of Sciences, Stockholm.
Frederick F. Thompson, Esq., New York.
Mrs. David P. Todd, Amherst.
Trübser \& Co., London, Engl. (Four copies.)
P. R. Uhler, Esq., Baltimore.

United States National Museum, Washington.
Vassar Brotimers' Institute, Puughkecpsie, N. Y.
Vassar College Library, Ponghkeepsic, N. Y.

Prof. A. E. Verrill, New Haveh, Coun. Watkinson Library, Hartford, Com.
Andrett G. Weeks, Jr., Esq., Boston.
Joun Jenner Weir, Esq., Beckenham, Engl.
Samuel Wells, Esq., Boston.
William Wesley \& Son, London, Engl. (Four copies.)
Oliver S. Westcott, Esq., Chicago, Ill.
B. Westermann \& Co., New York. (Two copies.)
Miss M. A. Willcox, Welleslcy.
Williams College Library, Williamstown, Mass.
Wilson Female College, Chambersburg, Penn.
Yale University Library, New Haven, Conn.

## EXPLANATION OF PLATE 1.

## Butterflies in color.-Nymphalidae, especially Satyrinae.

Printed in colur trom eight stonew ly Thomas sibelair and sun, after drawings ly L. Trouvelut. All of natural size. Where hoth surfaces are givan, the elothehed wings represent the under surface.

1. Cerryonis nephrle ㅇ. Botli surfaces.
2. Cercyonis uloque 9 . Both surfaces.
3. Enoctir purtlumetir ס Both strfaces.
4. Cereyomis nephele J. Upprer sulfiace.
5. Busitarohia archipmes $q$. Both sulfaces.
f. Ceperomis rolope $\delta$. Upper surface.
6. Anosir pueripules $\delta$. Both surfaces.
7. Cissiu curytus $\delta$. Both surfaces.
8. Oeneis semirlea. Jouly and upper surface of $\mathcal{F}$ : under surface of $\delta$.
9. Setyroules furyrice $\delta$. Both surfaces.

## EXPLANATION OF PLATE 2.

## Butterflies in color. - Nymphalidae (Nymphalinae).

Printed in color from eleven stones by Thomas Sinclair and Son, after drawings hy J. Henry Blake (figs. 1, 4-7, 9) and L. Trouvelot (figs. $2,8,8$ ). All are of matural size. Where both surfiles are given, the detached wings show the under surface.

1. Tremesset curlui. Both surfaces.
2. T'enpasir huntere $\delta$. Upper surface.
3. I'anessi huntera 9 . Both surfaces.
4. Euternesse amtiopel. Both smrfaces.
j. Busilarchin wihemis \& . Bothsurfaces.
5. Truessi atriluntü 9 . Both surfaces.
6. Aylais millorti. Both surfaces.
s. Betsilarlier astymmer of Both surfaces.
7. Presilmehin proseryina (cestyanar-arthemis) $\delta$. Both surfaces.

## EXPLANATION OF PLATE 3.

## Butterflies in color.-Nymphalidae (Nymphalidi).

l'rinted in color from cleren stulle by Thos. Sinchir and Son, after drawings hy J. Hemry Blake (tigs. 1-1, f-18) and Sichey L. Smith (his. 5). Natural size. Where both surfaces are given, the detarhed wings show the mader surface.

1. Polygunir comma iryas $\delta$. Buth surfaces.
2. Pulygonia futhns of. Lower surface.
3. Pulygonia comma hamisii J. Butlı surfaces.
4. Pulymenit comma dryers ㅇ. Lonver surface.
5. Polygunia proyme of. Buth surfaces.
f. I'olygrnicu funnes ठ. Both surfaces.
6. Pulyyonia comma hervisii $q$. Lower surface.
\&. Polygonia interrogrationis felbirbi of. Lower
7. Eugonia j-allum ס. Both surfaces.
8. Polyyonia interrayationis umbrase $\circ$. Lower surface.
9. Polygonia grucilis § Both surfaces.
10. Pulygonia interroyatimis fulmicii of. loth surfaces.
11. Polygonia interroytutionis umbrosit J. Both suıfaces. surface.

## EXPLANATION OF PLATE + .

Butterflies in color.-Nymphalidae, especially Argynnidi.

Printed in color from ten stones hy Thus. Sinclair and Son, after drawings by L. Trouvelot (tigs. 1-3. J.s) and f. A. Ponjade (tig. 4). Natural size. Where both surfaces are given, the detached wings show the under surface.

1. Argymnis aphrodite \&. Both surfaces.
2. Argynnis aphrodite J. Both surfaces.
3. Speyeria idalia f. Upper surface.
4. Hypatus bachmanii ס. Both surfaces.
5. Brenthis myrina ㅇ. Both surfaces.
6. Argynnis attantis $\delta$. Both surfaces.
7. Argynnis cybete $ᄋ$. Both surfaces.
8. Speyeria idalia §. Both surfaces.

## EXPLANATION OF PLATE 5.

## Butterflies in color. Nymphalidae (esp. Melitaeidi) and Lycaenidae (Chrysophanidi).

Printed in colors from eight stones by Thomas sinclair and Son, after drawings by L. Trouvelot (figs. 1-4, 6, 10, 13-15) and Silney L. Smith (figs. 5, 7-9, 11, 12). Natural size. Where both surfaces are given, the detached wings show the under surface.

1. Phyciodes tharos morpheus ס Both surfaces. This is the form called var. A by Edwards.
2. Euphydryas phaeton 9. Both surfaces.
3. Phyciodes tharos morpheus \&. Both surfaces. This is the form called var. B by Edwards.
4. Cinclidia harrisii $\delta$. Both surfuces.
5. Epidemia epixanthe 9 . Upper surface.
6. Charidryas nycteis 8 . Both surfaces.
7. Epidemia epixanthe ס. Both surfaces.
8. Fenisect tarquinius 9 . Both surfaces.
9. Chrysophanus thoe J. Both surfaces.
10. Cinclidia harrisii $\%$. Uppersurface.
11. Heades hypophlacas ठ. Both surfaces.
12. Chrysophanus thoe 8 . Upper surface.
13. Brenthis bellona $\delta$. Both surfaces.

I4. Brenthis montinus $\delta$. Both surfaces
15. Brenthis brllona q. Both surfaces.

$11$

## EXPLANATION OF PLATE 6.

## Butterflies in color.-Lycaenidae.

Printed in color from fifteen stones by Thos. Sinclair and Son, after driwings by J. Henry Blake. Natural size. Where both surfaces are given, the detached wings show the under surface.

1. Cyaniris pseudargiolue neglecta §. Both surfaces.
2. Calcphelis borealis J. Both surfaces.
3. Cyaninis pseudargiolus violacea o. Both surfaces.
4. Cyaniris pseudargiolus neglecta ㅇ. Upper surface.
5. Cyanivis pseudaraiolus vinlacea $\uparrow$. Upper surface.
6. Rusticus scudderii $\delta$. Upper surface.
7. Rusticus scudderii ․ Both surfaces.
8. Cyaniris pseudargiolus luciu ठ. Both surfaces.
9. Everes comyntas d. Both surfaces.
10. Everes comyntas ㅇ. Upper surface
11. Thecla liparops of. Both surfaces.
12. Cyaniris pseudargiolus lucia $f$. Both surfaces.
13. Thecla acadica d. Both surfaces.
14. Thecla calemus ㅇ. Both surfaces.
15. Thecla ontario ס. Both surfaces; copied from Edwards.
16. Thecla edwardsii d. Both surfaces.
17. Mitura damon \&. Both surfaces.
18. Nitura damon $\delta$. Botlı surfaces.
19. Incisalia irus $\delta$. Upper surface.
20. Uranotes melinus if. Both surfaces.
21. Incisalia niphon . Upper surface.
22. Incisalia irus. ㅇ. Both surfaces.
23. Incisalia niphon $\delta$. Both surfaces.
24. Strymon titus §. Both surfaces.
25. Incisalia augustus $\%$. Both surfaces.
26. Strymon titus $\ddagger$. Both surfaces.

## EXPLANATION OF PLATE 7.

## Butterflies in color. - Pierinae

Printed in color from twelve stones by Thos. Sinclair and Son, after drawings by J. Heury Blake (igs. 2-10, 12), Sidney L. Smith (fig. 1) and G. A. Poujade (fig. 11). Natural size. Where both surfaces are given, the detached wings show the under surface.

1. Pontia protodice protodice §. Both surfaces.
2. Pontia protodice protodice 8 . Both surfaces.
3. Pieris oleracea cruciferarum \&. Both surfaces.
4. Eurema lisa d. Both surfaces.
5. Euremu lisa ס. Both surfaces.
6. Eurymus philodice pallidice ㅇ. Both surfaces.
7. Eurymus interior interior ㅇ. Both surfaces.
8. Eurymusphilodice philodice $q$. Upper surface.
9. Eurynnus philodice ठ. Both surfaces.
10. Eurymus interior laurentina $\&$. Both surfaces.
11. Pieris rapae novangliae §. Both surfaces.
12. Pieris rapae rapae §. Both surfaces.

## EXPLANATION OF PLATE S. <br> Butterflies in color.-Papilionidae (Papilioninae).

Printed in color from fifteen stones by Thos. Sinelair and Son, after drawings by J. Henry Blake (figs. 1, 2, ob) and L. Trouvelot (figs. 3.4). All are of vatural size. Where both surfaces are given, the detacbed wings show the under suriace.

1. Jasoniades glaucus turnus ס. Both surfaces.
2. Euphoeades troilus §. Both surfaces.
3. Papilio polyxenes $\mathcal{f}$. Upper surface.
4. Euphoeates troilus 9 . Upper surface.
5. Papilio polyxenes $\delta$. Both surfaces.

## EXPLANATION OF PLATE 9. Butterflies in color.-Hesperidae (Hesperidi).

Printed in color on twelve stones ly Thos. Sinclair and Son, after drawings by G. A. Poujude (figs. 1-7, 9-14), L. Trouvelot (fig. 8) and J. Henry Blake (fig. 15). Natural size. Where hoth surfaces are given, the: detached wings show the under surface.

1. Thanaos persius d. Both surfaces.
2. Pholisora catullus $\delta$. Both surfaces.
3. Thans brizo 8. Both surfaces.
4. Thanaos lucilius $\delta$. Both surfaces.

ธ. Thoryles pylades ठ . Both surfaces.
6. Thanaos icelus d. Both surfaces.
7. Thanaos horatius $\&$. Upper surface.
8. Epargyreus tityrus ठ. Both surfaces.
9. Thanaos brizo 8 . Upper surface.
10. Thancos limatius ठ. Both surfaces.
11. Achalarus lycidas d. Both surfaces.
12. Thanaos martialis 子. Both surfaces.
13. Thanans jucenalis $\delta$. Both surfaces.
14. Thancoos jumenalis \&. UPper surface.
15. Thanars terentius \& . Both surfaces.

## EXPLANATION OF PLATE 10.

## Butterflies in color.-Hesperidae (Pamphilidi).

Printed in color from ten stones by Thos. Sinciair and Son, after drawings iy G. A. Poujade, - excepting figs. 1 and 19 which are by L. Trouvelot. All are of natural size. Where both surfaces are given, the detached wings show the under surface.

1. Amblyscirtes samoset $\%$. Both surfaces.
2. Pamphila mandan §. Both surfaces.
3. Amblyscirtes samoset §. Both surfaces.
4. Amblyscirtes vialis ठ. Both surfaces.
5. Erynnis metea $\delta$. Both surfaces.
6. Poanes massasoit $\wp$. Both surfaces.
7. Ancyloxipha numitor §. Both surfaces.
8. Atrytone zabulon zabulon $\ddagger$. Both surfaces.
9. Alrytone zabulon pocahontas $\%$. Both surfaces.
10. Atrytone zabulon d. Both surfaces.
11. Erynnis metea 9 . Upper surface.
12. Anthomaster leonardus f. Upper surface.
13. Erynnis sassacus 9 . Upper surface.
14. Anthomaster leonardus ठ. Both surfaces.
15. Thymelicus aetna ㅇ. Upper surface.
16. Erynnis sassacus §. Both surfaces.
17. Limochores taumas $\delta$. Both surfaces.
18. Polites peckius む. Both surfaces.
19. Thymelicus aetna ठ. Both surfaces.
20. Linochores bimacula $\%$. Upper surface.
21. Limochores tuamas $\oint$. Upper surface.
22. Polites peckius ㅇ. Upper surface.
23. Limochores manataaqua $\ddagger$. Upper surface.
24. Limochores bimacula む. Both surfaces.
25. Thymelicus mystic ठ. Upper surface.
26. Thymelicus mystic $\%$. Both surfaces.
27. Euphyes verna 9 . Upper surface.
28. Limochores manataaqua $\delta$. Both surfaces.
29. Euphyes metacomet if. Both surfaces.
30. Euphyes metacomet $\delta$. Upper surface.
31. Lerema hianna ठ. Both surfaces.
32. Lerema hianna ㅇ. Upper surface.
33. Euphyes verna §. Both surfaces.

## EXPLANATION OF PLATE 11.

## Butterflies in black.-Nymphalidae.

Printed at the De Vinue Press from new electrotypes from the original woodents enirived by Henry Maral for the third edition of Hurris's Inserts injurions to vegetation. In figs. 1, 3, 4, 5,6 and 8 the midhe pair of legs is shown in front. Where both surfaces are given, the under surface is at the right.

1. Curcyonis nephele. Both surfaces.
2. Satyrules eurydice. Both surfaces.
3. Eubunessa antiopa. Both surfaces.
4. Cissia eurytus. Both surfaces.
5. Ocneis semidea. Both surfaces.
6. Pulygoniu interoyrationis. Upper surface.
7. Busitarchie archippus. Both surfaces.
8. Cercyomis alope. Both surfaces.

## EXPLANATION OF PLATE $1 \Omega$.

## Butterflies in black.-Nymphalidae (Nymphalinae).

Printed at the De Vinue Press from new electrotypes from the original wonlonts engraved lyy llemry Marsh for Harris's Inseets and lent by C. L. Flint. Esi. Lu figs. $1,2,3,4,11$ and 12. the millle pair of logs, is shown in front. Where both surfaces are shown, the under sible is at the right.

1. Phycionles tharos marcia $\delta$. Both surfaces.
2. Euphydryas phaeton. Both surfaces.
3. Phyciodes tharos marcia 8 . Both surfaces.
4. Brenthis myrina. Both surfaces.
๖. Vanessa atalanta. Both surfaces.
(b. Brenthis bellona. Both surfaces.
5. Vanessa cardui. Both surfaces.
6. Brenthis bellona. Sicle viow, showing under surface.
7. Venessa hunteril. Both surfices.
8. Aglais milberti. Upper surface.
9. Argimmis aphrohlite. Both surfaces
10. Speyeria ilulia. Both surfaces.

## EXPLANATION OF PLATE 13.

## Butterflies in black.-Lycaenidae, Papilionidae, Hesperidae.

Printed by the De Vinne Press from new electrotypes from the original woulcuts engraved by Henry Marsh for the third edition of Harris's Iusects injurious to ve retation, and lent by C. L. Flint, Ewi. Where both surfaces are shown, the under side is at the right.

1. Incisalia miphon. Botly surfaces.
2. Atrytone zabulon. Both surfaces.
3. Pieris oleracea. L†puer surface.
4. Jasoniades glaucus. Both surfaces.
5. Incisalia augustus. Both surfaces.
6. Authomaster lconamlus §. Both surfaces.
7. Cyaniris pseudargiolus luria d. Upper sur-
8. Polites peckius ठ. Both surfaces.
9. Heodes hypophlapas. Both surfaces.
10. Eurymus philorlice 9 . Both surfaces.
11. Ancyloxipha numitor. Both surfaces.
12. Polites peckius \&. Both surfaces.
13. Thorybes pylades. Botlı surfaces.
14. Cyantris pseudargiolus lucia. Nicle riew with under surface. face.
15. Eurymus philodice 8. Both surfaces.

E De Vimme Press.

## EXPLANATION OF PLATE 14.

## Butterflies in black. - Mostly Nymphalidae and Lycaenidae.

Electrotyped and printed at the University Press from wood cuts engravel by John Andrew and Son. When both surfaces are shown the under surface is at the left. All are of natural size.

1. Polygonia satyrus $\delta$. Both surfaces; California.
2. Everes comyntas ס. Both surfaces.
3. Polygonia faunus ठ. Both surfaces.
4. Euptoieta claudia f. Both surfaces; Massachusetts.
5. Phyciodes batesii ठ. Both surfaces; New York.
6. Eroru late $\delta$. Upper surface; copied from Edwards's Butterflies of North America.
7. Neonympha phocion 万. Both surfaces; Georgia.
8. Nomiades couperi $\delta$. Both surfaces; Anticosti.
9. Erora lacta f. Both surfaces; engraved from a photograph by John M. Blake; specimen lent for the purpose by the Yale College museum. Maine.
10. Vomiades couperi ㅇ. Both surfaces; Anticosti.
11. Thecla calamus $\delta$. Both surfaces.
12. Heraclides cresphontes $\delta$. Both surfaces; from a specimen reared by Mr. HI. S. Scagrave, from caterpillars found in the Botanic Garden, Cambridge.
13. Uranotes melinus. Both surfaces.
14. Polyyonia sutyrus ㅇ. Under surface; California.
15. Junonice coenia $\delta$. Both surfaces; from a specimen taken in Massachusetts by Mr. F. H. Spraguc.
16. Calephelis borealis 8. Both surfaces; Illinois.
17. Oeneis jutta ㅇ. Both surfaces; from a specimen captured in Maine by Mr. Carl Braun.

## EXPLANATION OF PLATE 15.

## Butterflies in black.-Papilionidae, Hesperidae.

Electrotyped and printed at the University Press from woodeuts engraved ly John Andrew and Son, after photograplas. Where both surfaces are shown, the ander inrface is at the left.

1. Eudamus proteus $\delta$. Both surfaces; Georgia.
2. Thanaos ausonius $\delta$. Both surfaces; from the type, by favor of Mr. J. A. Lintner; New York.
3. Epargyreus tityrus $\delta$. Both surfaces: New England.
4. Eurymus eurytheme ठ. Both surfaces; Iowa.
5. Hesperia centoureae J. Both surfaces; Labrador.
6. Eurema lisa f. Epper surface; New England.
7. Eurymus eurytheme \&. Upper surface; Mississippi Valley.
8. Eurymus interior d. Upper surface: Cape Breton.
9. Hesperia montivaga 万. Botlı surfaces: Missouri.
10. Tunthidid micipne \&. Both surfaces; West Virginia.
11. Iphiclides ajax d. Both surfaces; West Virginia.
12. Iunthirlia nicippe $\delta$. Both surfaces; West Virginia.
13. Anthocharis genutia d. Both surfaces; Pennsylyania.
14. Callitryas cubule 子. Both surfaces; Floridla.
15. Anthocharis genutia 8 . Upper surface; Texas.
16. Callidryas malule of. Bothsurfaces: Florida.

## EXPLANATION OF PLATE 16.

## Butterflies in black.-Nymphalidae, Papilionidae.

I'tinted at the University Press. The woodeuts from diferent sources. Figs. 1-5, 7, 9, 10 were purehased of C. V. Riley; fig. 6 was engraved by Henry Marsh after a drawing by J. Hemry Blake; and fig. 8 was lent by Dr. A. S. Parkard. All are of matural size.

1. Puntia protodice \&. Upper surface.
2. Pimtia protulice 8. Upper surface.
3. Larrtiusphitenor. Upper surface.
4. Pieris rapac \&. Epper surface.
5. Pieris rapue 3 . Tupper surface.
f. Protryas persephone, a fossil butterfly from the tertiaries of Colorado, of the family Nrmphalidae.
6. Chloripipe clyton $\delta$. Upper surface; the dotted liue indicates the contour of the left wings of the female.
7. Pulygonia mrogne. Both surfaces, the under on the right.
8. Chlorippe clyton ठ. Under surface.
9. Anosia plexipus $\delta$. Epper surface.

## EXPLANATION OF PLATE 17.

## Butterfies in black.-Hesperidae.

Reprotued by photoravire from indiatink drawings by J. Henry blake. All the figures are of matural size, and where both surfaces are shown, the left is the under side. Printed without redurion by the Buston Photogravure Co.

1. Erynnis manitola 우. Both surfaces; Coloralo.
2. Limochores pontiac \&. Lpper surface; lllinois.
3. Lerenu accius §. Upper surface; Alabama.
4. Erymis manitola ठ . Both surfaces; British Columbia. The same specimen served for the illnstration in the Memoirs Bost. soc. mat. hist., ii. pl. 10. fig. 11 .
5. Limochores pontice ठ. Both surfaces; New York.
6. Oligoria maculato. Both surfaces; Florida.
7. Lerema accius 우. Both surfaces; Alabama.
\&. Atalopeles heron ㅇ. Upper surface: Missouri.
8. Erynnis attalus $\%$. Upper surftee: T exas. Drawn from the type of Ocytes seminole.
9. Hyle thila phylams d. Both surfaces: Alabama.
10. Thymelicus liveturs of. Botlo surfaces.
11. Eryunis attalus $\delta$. Both surfaces.
12. Ilylophila phylaws 8 . Upper surface; Floridla.
13. Calpodes ethlius. Both surfaces.
14. Thymelicus lirttus $¢$ ¢ Upper surface.
15. A/alopedes huron $\delta$. Both surfaces; Texas.
16. Itrytone logan \& $\ddagger$. Both surfaces; Rhode Island.
17. Thorylues bathyllus. Both surfaces; Massachusetts.
18. Atrytone logan $\delta$. Upper surface; Iowa.
19. Phyranassa vialor. Both surfaces; Massaclinsetts

# EXPLANATION OF PLATE 18. <br> Geographical distribution in North America.- Nymphalidae (Euploeinae. Satyrinae). 

Printed in color by Julius Bien d Co.

1. Distribution of Anosia plexippus.
2. Distribution of Cereyonis nephele.

Satyrinae.
む. Distribution of Enodia portlaudia.
2. Distribution of Oeneis jutta.
6. Distribution of Satyrodes eurgrlice.
3. Distribution of Cercyonis alope.
7. Distribution of Neonympha phocion.
8. Distribution of C'issia eurytus.

Butlerflies of New England

## EXPLANATION OF PLATE 19.

## Geographical distribution in North America.-Nymphalidae (Nymphalinae)

## Printer in color by Thlin* Bien © © ©

## APATUIIDI.

1. Distribution of Chlorippe clytom.

2. Distribution of Besilurchie urchippus.
3. Distribution of Basiletrchie erstyanax.
4. Distribution of Basilurcleire proserpine (esty-unax-arthemis).
$\therefore$ Distribution of Besilarchie erthemis.
V.ANEssill.
5. Distribution of Polygoniu mogne.
6. Distribution of Paly!gomiat gractilis. The belt in the extreme north-west indicates the presence of the species in Maska.
s. Dintribution of Poly!gonín jutuns.

Butterflies of New Engtand

$\qquad$

EXPLANATION OF PLATE $\Omega_{0}$.

Geographical distribution in North America.-Nymphalidae (Nymıphalidi).

Jrinted in color ly Julius Bien \& Co.

1. Distribution of Polygonio settyrus.
2. Distribution of Eucanesser mutimpe.
3. Distribution of Polygunit comma.
4. Distribution of Itfris milherti.
3 Distribution of Prolygonin interrograti atis
5. Distribution of $\mathrm{J}^{\text {renen}}$.ese atulenter.
4 Distribution of Eergoniar j-ellhum.
6. Distribution of Temessel henterer.

Butterflies of New England

## EXPLANATION OF PLATE 21.

Geographical distribution in North America.-Nymphalidae (Nymphalinae, Libytheinae).

Printed in color by Julins Bien dicu.

NYMPHALIDI.

1. Distribution of I'enessat cardui.
2. Distribution of Junonit copnict.

HETYNNHI.
3. Distribution of Euptoirta ritulutire.
4. Distribution of Speyeriu irlatire.
5. Distribution of Argymuis rybele.
6. Distribution of fraynnis uphroalite.
7. Distribution of Arg! $/$ mhis utluntis. LIMCTHENNAE.
8. Distribution of Hypatus bachmanii.

## EXPLANATION OF PLATE $\Omega$ 。

Geographical distribution in North America. - Nymphalidae (Nymphalinae), Lycaenidae (Lemoniinae).

Printed in color by Julius Bien of Co.

## ARGY゙NNIDI.

1. Distribution of Brenthis myrina. Tlie extension of the color to the extreme north-west indicates the presence of the speeies in Alaskia.
2. Distribution of Brenthis bellona.
melitaeidi.
3. Distribution of Phyciodes tharos.
4. Distribution of Phyciudes batesii.
5. Distribution of Charidryas myctpis.
6. Distribution of Cinclidiu harrisii.
7. Distribution of Euphydryas phacton.

LEMONINAE.
8. Distribution of Calephelis borealis.

Mes

$\qquad$

## EXPLANATION OF PLATE 23. <br> Geographical distribution in North America.-Lycaenidae (Theclidi).

L'rinteal in color by Julius Bien do Co.

1. Distribution of Strymom titus.
2. Distribution of Inriselie angustus.
3. Distribution of Erura lufla.
(i. Distribution of Crenones melinus.
4. Distribution of Imcisaliu miphom.
5. Distribution of Viture detmone.
6. Distribution of Incisaliu irns.
7. Distribution of Thesle omterio.

## EXPLANATION OF PLATE 24. <br> Geographical distribution in North America.-Lycaenidae (Lycaeninae).

Printed in color y Julius Bien \& Co.

THECLIDI.

1. Distribution of Theela liparops.
2. Distribution of Thecla calanus.
3. Distribution of Therla edwardsii.
4. Distribution of Thecla acalica.

LYC.SENHI.
5. Distribution of Everes comyntas. C'entral California sliould hare been incIuded.
6. Distribution of Cyaniris pseudargiolus; the oblique bars indicate the special range of $\mathrm{C} \cdot \mathrm{p}$. lucia; the vertical bars that of $C$. p. piasus; and the horizontal bars of $C$. $p$. violacea nigra. The oblique bars in the extreme left upper corner indicate the occurrence of C. p. lucia in Alaska.
7. Distribution of Nomiaules couperi.
8. Distribution of Rusticus scudderii.

# EXPLANATION OF PLATE 25. <br> Geographical distribution in North America.- Lycaenidae (Lycaeninae), Papilionidae (Pierinae). 

Printed in color by Julius Bien \& Co.

CIIRYSOPIIANIDI,

1. Distribution of Chrysophamus thoe.
2. Distribution of Epidemia epixanthe.
3. Distribution of Ifeodes hypophlaeas.
4. Distribution of Feniseca terquinius.

RHODHCEMEDE
5. Distribution of Callidryas eubule.
6. Distribution of Eurymus interior.
7. Distribution of Eurymus phitodice.
8. Distribution of Eurymus eurytheme.

## EXPLANATION OF PLATE 26.

## Geographical distribution in North America.-Papilionidae.

## Printed in color by Julins Bien \& Co.

## RHODOCERED.

1. Distribution of Itenthitia nicippe.
2. Distribution of Eurema lisa.

INTHOCHARIDI.
3. Distribution of Anthorharis yruutir. PHERBDI.
4. Distribution of Pontia pratodice.
5. Distribution of Pieris oleracea.

PAPHIONINAE.
6. Distribution of Laprtios philenor.
7. Distribution of Iphiclides ajux.
8. Distribution of Jetsoniates glaucus. The barred portion indicates the special range of $J . g$ glaucus.
** The distribution of Pieris rapae is given on a separate folding map.

## EXPLANATION OF PLATE $\simeq 7$. <br> Geographical distribution in North America.-Papilionidae, Hesperidae.

Printed in color by Julius Bien if Co.

## PAPILIONNN:

1. Distribution of Euphoeades troilus.
2. Distribution of Heraclides cresphontrs. Some localities mentioned in the text were learned since the printing of the map.
3. Distribution of Papilio polyxenes.

HLSPLERIM.
4. Distribution of Eudamus proteus.
5. Distribution of Epargyreus tityrus.
6. Distribution of Achalarus lycidas.
7. Distribution of Thorybes bathyllus.
8. Distribution of Thoryles pylades.

Butterflies of New Engiand

## EXPLANATION OF PLATE 28.

Geographical distribution in North America.-Hesperidae (Thanaos).
Printed in color by Julius Bien \& Co.

1. Distribution of Thanaos persius.
2. Distribution of Thenaos martialis.
3. Distribution of Thanaos lucilius.
4. Distribution of Thanaos terentius.
5. Distribution of Thannos icelus.
6. Distribution of Thanaos juvenalis.
7. Distribution of Thanaos brizo.
8. Distribution of Thanaos horatius.

## EXPLANATION OF PLATE 29.

## Geographical distribution in North America.-Hesperidae.

Printed in color by Julius Bien d Co.

HESIPRRID1.

1. Distribution of Pholisora catullus.
2. Distributiou of IIesperia montivaga.
3. Distribution of Hesperia centaureap. *

PAMPHILIDI.
4. Distribution of Ancyloxipha numitor.
5. Distribution of Pamphila mandan. The belt in the upper left hand corner indicates its occurrence in Alaska.
6. Distribution of Amblyscirtes vialis.
7. Distribution of Amblyscintes samoset.
8. Distribution of Poanes massasoit.

## EXPLANATION OF PLATE 30.

## Geographical distribution in North America.-Hesperidae (Pamphilidi).

Printed in color by Julius Bien \& Co.

1. Distribution of Phycanassa viator.
2. Distribution of Erynnis sassacus.
3. Distribution of Atrytone logan.
4. Distributiou of Erynnis manitoba.
5. Distribution of Atrytone zabulon.
6. Distribution of Erynnis metea.
7. Distribution of Hylephila phylaeus.
8. Distribution of Erynnis attalus.

## EXPLANATION OF PLATE 31. Geographical distribution in North America.-Hesperidae (Pamphilidi).

Printed in color by Julius Bien it Co.

1. Distribution of Atalopedes huron.
2. Distribution of Thymelicus brettus.
3. Distribution of Anthomaster leonardus.
4. Distribution of Thymelicus mystic.
5. Distribution of Polites peckius.
6. Distribution of Euphyes metacomet.
7. Distribution of Thymelicus aetna.
8. Distribution of Euphyes rerna.

Butterflies of New Engiand

## EXPLANATION OF PLATE 32.

Geographical distribution in North America.-Hesperidae (Pamphilidi).

Frinted in color by Julius Bien d Co.

1. Distribution of Limochores bimacule.
2. Distribution of Limachores manatruqua.
3. Distributinn of Limochores taumas.
4. Distribution of Limuchares pontint.
5. Distribution of Crelpodes eth7ius.
G. Distribution of Oligoria maculata.
6. Distribution of Lerema accius.
*. Distribution of Lerema hianna.

Butterflies of New Ensland

## EXPLANATION OF PLATE 33.

## Male abdominal Appendages.-Nymphalidae.

For uearly all the figures of this plate I am indebted to my friend Edward Burgess, Esq. Figs. 21, 32, 36 and 39 are by J. Il. Emerton. Figs 10a and 29a by myself. All show a side view, unless otherwise speeified.

1. Cercyonis alope $\frac{13}{1}$.
2. Sutyrodes eurydice ${ }_{13}$.
3. Enodia portlandia $\frac{13}{1}$.
4. Oeneis semkilea $\frac{13}{1}$.
5. Oeneis juttet $1_{1}^{3}$.
G. Cissin eurytus $\frac{13}{13}$. Top view of upper organ.
6. Cissia eurytus $\frac{13}{1}$.
7. Seonympha mhacion $\frac{13}{13}$.
8. Basilurchia arthemis $\frac{13}{1}$.
9. Chlorimpe clyton $\frac{13}{1}$. 10a, top view of extremity of upper organ.
10. Basiletrchia arelimmes $\frac{13}{1}$.
11. Busilarchia archippus ${ }_{1}{ }^{3}$. Clasp seen from the micklle.
12. Polygomia progne $\frac{18}{1}$.
13. Polygonia comma $\frac{18}{1}$.
14. Dusilurckia astyunax $1_{1}^{13}$.
15. Pulyyのnia feunus $\frac{18}{1}$.
16. Eugonia j-album ${ }_{13}^{13}$.
17. Eugonia j-album $\frac{13}{1}$. Inside view, with right clasp removed.
18. Polygonia intemogutionis $\frac{18}{1}$. Inside view, with right clasp removed.
19. Polygomia interogationis $\frac{1 e}{1}$.

21: Pulygonire gracitis $\frac{18}{1}$.
22. T'messa huntera ${ }_{13}{ }^{3}$.
23. Anosire pleximpus $\frac{8}{1}$. The false clasp forming a part of the eighth segment almost cntirely conceals the real clasp.
24. Anosia plexippus $\frac{8}{1}$. The eighth segment removed, exposing the whole of the real clasp.
25. Aglats milberti $\frac{13}{1}$.
26. Aglais milberti ${ }_{1}^{13}$. Top view of right half.
27. Euranessa antiopa $\frac{13}{1}$. Inside view, with right clasp remored.
28. Euvanrssa antiopa $\frac{13}{1}$.
29. T'enessa utalantu ${ }^{13}$. 29a, top view of tip of upper organ.
30. Junomive coenia $\frac{13}{1}$.
31. Vemesst cardui $\frac{13}{1}$.
32. Polygomin satyrus $\frac{18}{1}$.
33. Brenthis myrina $\frac{18}{1}$. Top view of tip of upper orgall.
34. Brenthis myrina $\frac{18}{1}$. Distal half of rierht clasp from beneath.
35. Brenthis myrina $\frac{18}{1}$.
36. Argynnis atlantis $\frac{10}{1}$.
37. Euptoicta claulia $\frac{18}{1}$.
38. Brentle is hellonat $\frac{18}{1}$.
39. Brenthis bellona $\frac{18}{1}$. Inferior view of clasps.
40. Arofynis raplrodite $\frac{10}{1}$.
41. Brentlis montinus $\frac{18}{1}$.
42. Bremthis montinus $\frac{8}{1}$. Extremity of right clasp from beneath.
43. Speyeriu inlulies 10.
44. Arymmuis cybete $\frac{10}{1}$.

## EXPLANATION OF PLATE : 34.

## Male Abdominal Appendages.-Nymphalidae (Melitaeidi, Libytheinae) and Lycaenidae.

Most of the figures were kindly drawn for me by Elward Burgess. Esid. Fig- 3. 4, 10-13, 17-19, 26, 27, 30 , 31 and 38 are ly J. H. Emerton. Unless otherwise specified, all sbow a side vien. Lithography by B. Meisel.

1. Phyciodes tharos $\frac{18}{2}$.
2. Plyciodes tharos $\frac{18}{1}$. Top view in ontline, somewhat diagrammatic.
3. Euphydryas phaeton $\frac{18}{1}$. Posterior view, the hairs left on one side.
4. Euphydryas phaeton $\frac{18}{1}$.
5. Charidryas nycteis $\frac{18}{1}$.
6. Charidryas nycteis $1_{1}^{18}$. End view of right clasp, or from the top of fig. 5.
7. Cinclulia hawisii $\frac{18}{1}$. Upper organ not shown.
8. Cinclidia harrisii $\frac{18}{1}$. End view of right clasp.
9. Phyciodes batesii $\frac{18}{1}$.
10. Catephelis borealis $\frac{18}{1}$.
11. Calephelis linreatis $\frac{18}{1}$. Posterior view.
12. IIypatus bachmanit $\frac{18}{1}$.
13. Hypatus bachmanii $\frac{18}{1}$. Right clasp remored to show interior aspect and hook of upper organ.
14. Theela edeardsii $\frac{18}{1}$.
15. Thecle ontario $\frac{18}{1}$.
16. Thecla ueadica $\frac{18}{2}$.
17. Thecla liparops ${ }_{1}^{18}$. Top view.
18. Thecla liparops $\frac{18}{1}$. Posterior view.
19. Theclu liparops $\frac{14}{1}$.
20. Uremotes melinus $\frac{18}{1}$.
21. Incisatia niphon $\frac{18}{1}$.
22. Incisalia irus $\frac{18}{1}$.
23. Strymon titls $\frac{18}{1}$.
24. Therla calemus $\frac{18}{1}$.
25. Thecla calanus ${ }_{1}$. View from below in ontline.
26. Eceres comyntes $\frac{25}{1}$. Posterior view from below.
27. Everes comyntas $\frac{25}{1}$.

2ヵ. Mitura drman $\frac{18}{1}$.
29. Rusticus scuddroii $\frac{18}{1}$.
30. Tomiades rouperi $\frac{25}{1}$. The drawing has mufortunately been engraved upside down.
31. Vomiades couperi ${ }_{1}^{25}$. View from beneath.
32. Incisulice augustus $\frac{18}{1}$.
33. Cyaniris pseulargiolus $\frac{25}{1}$.
34. Cymenis pseudargiolus $\frac{25}{12}$. Posterior view.
35. Fenisect temquinius $\frac{18}{1}$.
36. Epidemia ${ }^{\text {ppixunthe }} 1^{18}$.
37. Chrysuphanus thoe $\frac{18}{1}$.
38. Hewtes hyprophlaeas $\frac{25}{1}$.

## EXPLANATION OF PLATE 35.

## Male Abdominal Appendages.-Papilionidae, Hesperidae.

All the dissections and drawings were made by my friend Elward Burgess, Esq., exeepting figs. 3, 21-23 by J. II. Emerton and fig. 43 by myself. Unless otherwise stated, they represent side view

## PAPILIONIDAE.

1. Callirlryas enbule $\frac{9}{1}$. Upper organ not seen.
2. Callidryas eubule $\frac{9}{1}$. Interior view by removal of right clasp.
3. Eurymus interior 13. Upper organ not seen; part of eighth abdominal segment removed.
4. Evrymus philodice $1_{1}^{3}$. Upper organ not seen.
5. Eurymus philodice $\frac{13}{13}$. Eighth segment removed.
6. Eurymus eurytheme $\frac{13}{1}$.
7. Fanthidia nicimpe $\frac{18}{1}$.
8. Ianthidia nicimpe $\frac{18}{1}$. Edge of right clasp, seen from behind.
9. Ianthilia nicippe 13. Upper organ nearly concealed.
10. Pieris rapae ${ }_{13}^{13}$.
11. Eurema lisa $\frac{18}{1}$.
12. Eurema lisa $\frac{18}{2}$. Outline of clasps from behind.
13. Euremalisa $\frac{18}{1}$. Upper organ.
14. Anthocharis genutia 18.
15. Pieris oleracea $\frac{14}{1}$.
16. Pieris alerafea $\frac{14}{1}$. Extremity of upper organ.
17. Pontia protodice $\frac{13}{1}$. Upper organ.
18. Pontia protodice $\frac{13}{1}$.
19. Euphoedes troilus $\frac{13}{1}$. Iuterior view of left clasp.
20. Euphoeades troilus ${ }_{1}^{13}$. Extremity of toothed spine, seen from above.
21. Meraclides cresphontes $\frac{9}{1}$. Interior view of left clasp.
22. Heraclides cresphontes $\frac{9}{1}$. Extremity of upper organ.
23. Herurlides resphontes $\frac{9}{1}$. Top view.
24. Lacrtias philenor i. Interior view of left clasp.
25. Laertias philenor $\frac{9}{1}$.
26. Iphiclides ajax $1_{1}^{3}$. Interior view of left clasp.
27. Iphicliles ajax $\frac{1}{2}^{3}$. The upper organ seen by removing a part of the eighth abdomiual segment.
28. Ipliclides ajax $\frac{13}{1}$. Top view of extremity of upper organ.
29. Iphiclides ajax $\frac{9}{1}$. Fighth segment mostly in place, concealiug upper organ.
30. Pamilio polyrenes $\frac{9}{1}$.
31. Josoniades glaurus $\frac{9}{1}$. Interior view of left clasp.
32. Jasoniales glancus $\frac{9}{1}$.
33. Jasoniades glaucus $\frac{9}{1}$. Tip of curved spine, seen from behind.
34. Jasoniucles glaucus $\frac{\text { g. }}{1}$. Extremity of eighth abdominal segment.

HESPERIDAE.
35. Thorybes mylates $\frac{13}{2}$.
36. Epary!reus tityrus $\frac{1}{1}^{3}$.
37. Eudamus proteus ${ }_{1}^{1 \frac{1}{1}}$.
88. Tharybes bathyllus $1_{1}^{3}$.
39. Ifesperia montivagus $\frac{18}{1}$. Clasp.
40. Ifesperiu montivagus $\frac{18}{18}$. Upper organ.
41. Phohisura catullus 18. Clasp.
42. Pholisora catullus 18. Upper organ.
43. Pholisora catullus in. Fxtremity of upper organ from aloove.
44. Achalaruslycidas $\frac{18}{1}$.
45. Hespria centurareue 18.

## EXPLANATION OF PLATE 36.

## Male abdominal appendages.-Hesperidae (Thanaos).

With the exception of Fig. 33 (by J. I1. Emerton), all the original drawings were mitle by my friend Edward Burgess, Eirg, and are mitritied twenty diameters. The clasps of the two sides are drawn separately to show the asymmetry.

1. Thanaos persius. side view of upper organ.
2. Thanaos persius. Side view of left clasp.
3. Thanaos persius. Side view of right clasp.
4. Thanaos lucilius. Side view of upper organ
5. Thanaos lucilius. Side view of left elasp.
6. Thanaos Tucilius. Side view of right clasp.
7. Thancus bizo. side view of upper organ.

太. Thanaos brizo. 'Top view of upper' organ.
9. Thanaos brizu. 'Top view of left clasp.
10. Thanaos bri:o. Top view of right elasp.
11. Thanaos brizo. Nide view of left clasp.
12. Thancos brizu. Side view of right clasp.
13. Thenaos horatius. Side view of upper organ.
14. Thanaos horatius. Posterior face of upper part of upper orgat.
15. Thanaos horatius. side view of left clasp.
16. Thanaos horatius. Side view of right clasp.
17. Thanaus terentius, side vicw of upper organ.

1s. Thanaus tromitus. Side view of left clasp.
19. Thamaos torentius. Nisle view of rimht clasp.
20. Thanaos terentius. Top view of extremity of mpper orqan.
21. Thandos martialis. Side view of upper or๙an.
22. Thanaos martialis. Sille vicw of left clasp.
23. Thanaos martialis. Side view of right clasp.
24. Z7hanaos jueenalis. Sicie view of upper organ.
25. Thanaos juvenalis. Sicle view of left elasp.
26. Thanaos jucenalis. Side view of right elasp.
27. Thannos jurenalis. Posterior face of upper organ.
23. Thanuws terentius. 'Top view of left elasp.
29. Thanaus terentius. Top ץiew of right clasp.
30. Thancos icelus. Side view of upper organ.
31. Thanaos icelus. Sile view of left clasp.
32. Thanaus icelus. Sicle view of right clasp.
33. Thanaas ausonius. Side view of end of right clasp, witi: inner view of tip of left clasp.
:34. Thancos jurenalis. Top view of left clasp.
35. Theanas jumnalis. Top view of right clasp.

## EXPLANATION OF PLATE 37.

## Male Abdominal Appendages.-Hesperidae (Pamphilidi).

All the drawings and the orginal dissections were kindly made by my frieul, Edward Burgess, Esf., excepting Figs. 7 and 33 , which were drawn by J. If. Fmerton. All are magnified righteen diameters, excepting fig. 3, which is magnified twenty-tive diameters.

1. Aucyloxipha mumitor: Side view.
2. Pamphila mandan. Side view.
3. Amblyscintes vialis. Side view.
4. Amblyscirtes samoset. Side view.
5. Evynmes manitola. Side view.
6. Erymnis metea. Side view.
7. Evynnis attalus. Side riew.
8. Poanes massasoit. Side riew.
9. Ermnis manitoba. Interior view of tip of clasp.
10. Phycanassa viator. Side view.
11. Atrytone logan. Side view.
12. Lerema accius. U'pper organ from above.
13. Hylepltila phylaeus, Side vicw.
14. Erynnis sassacus. Side view.
15. Thymelicus atma. Side view.
16. Limochores taumas. Side view
17. Atrytone zabulon. Posterior view of tip of clasp.
18. Atrytone zalulom. Side view.
19. Poanes massasuit. Top view of upper organ.
20. Erynnis sussacus. Interior view of tip of clasp.
21. Atalopedes huron. Tip of upper organ from above.
22. Atalopedes huron. Side view.
23. Euphyes metacomet. Side view.
24. Polites peckius. Side view.
25. Polites peckius. Interior view of tip of clasp.
26. Anthomaster leonardus. Side view.
27. Thyneplicus brettus. Side view.

## EXPLANATION OF PLATE 38. <br> Outline and Neuration of Wings.-Nymphalidae.

Drawa in ink by J. H. Emertou from bethed specimens. Ihotographic relief-plate prepared ly the boston Photogravure Co. Irrinted at the Univerity lress. The complete flyures are all of uatural size; the others enlarged $\frac{3}{2}$.

1. Cereyomis nephele.
2. Inosiu ilexippus.
3. Cissict eurytus.
4. Nat!rorles eurylice.
5. Oeneis semülea.
6. Enodia portlemdir.
7. Teonymphre phocion.
8. Eugonia j-album.
9. Busilarchia arthemis.
10. Polygonia commer.
11. Chlorippe clytom.
12. I'anessa huntera.
13. Agluis milberti. The independent sketch in the cell shows, on a larger scale, the origin of the nervules next the upper apex of the cell.
14. Junonia coenia.
15. Euranessa antiopu. The indepenclent sketeh in the cell is as in tig. 13.

Butterflies of New Enstand.
Plate 38.

## EXPLANATION OF PLATE 39.

## Oatline and Neuration of Wings.-Nymphalidae, Lycaenidae.

Drawn in ink by J. II. Emerton from bleached specmens. Photographie relief-plate preparell iy the Boston Phetogravire Co. The complete figures nmmbered 1 to 9 are of natural size, thone numbered 10 to 24 eulrged $\frac{3}{2}$; the enlargen portion of the front wing is in the one case $\frac{3}{2}$, in the other ${ }_{1}^{2}$.

NYMPHALIDAE.

1. Euphydryas phctoton.
2. Speypria idalia.
3. Cinclilia hemisii.
4. Euptoietr claudia.
5. IIypatus bachmemii.
6. Ligymmis atlautis.
7. Brenthis myrina.
8. Phyciodes tharus.
9. Charidryas nycteis.

LYC.AENTDAE
10. Calephelis boreulis. The intermal nervure of fore wings and precostal nervure of hind wings not shown.
11. Thecla eduardsii.
12. Tronotes melinus.
13. Incisulite niphon. The tigure does nut properly show the apical excision of the imer margin of tha hind wing.
14. Hiturat demon.
15. Strymon titus.
16. C'yamiris pseudargiotus.
17. Eroru lactu. Lowest suberostal nervile of hind wing accidentally omitterl.
18. Rusticus scmulerii.
19. Nomirutes iouperi.
20. Eicres comyntas.
21. Heates hymnphlueas.
22. Epidemits episunthe.
23. Chr!!srqhermus thoe.
24. Feniserve toryuinius.

## EXPLANATION OF PLATE 40 .

## Outline and Neuration of Wings.-Papilionidae.

Drawu in ink by J. 1I. Emerton from bleached specimens. Photographic relief-plate prepared by the hoston Photogravure Co. The eomplete figures are of the natural size; the others enlarged $\frac{3}{2}$.

1. Papilio polyxenes.
2. Pieris olerarea.
3. Callidryas eutule.
4. Laertias phitenor.
5. Euphofades troilus.
6. Fantherlir nirimp.
7. Eurema lisa.
8. Jasomiades gluucus.
9. Anthocharis genutia.
10. Eurymus phitodice.
f. Pontia protodice.

## EXPLANATION OF PLATE 41.

Outline and Neuration of Wings.-Papilionidae (Papilioninae), Hesperidae (Hesperidi).

Drawn iu ink by J. H. Emerton from bleached specimens. Photographie relief-plate prepared by the Bostou Photogravure Co. Fig. 1 is of natural size, the separate part of fore wing $\frac{3}{2}$; fig. 4 is $\frac{2}{3}$ natural size, the separate part of fore wiug $\frac{1}{1}$ : all the others are enlarged $\frac{3}{2}$, the separated parts of fore wings $\frac{2}{1}$.

1. Iphiclides ajax.
2. Eudamus proteus.
3. Epargyreus tityrus.
4. Thorybes pylades.
5. Heraclides cresphontes.
6. Achalarus lycilas.
7. Thanaos juvenalis.
8. Pholisora catullus.
9. Hesperia montivagus.

Butterflies of New England.
Plate 41

## EXPLANATION OF PLATE 42.

## Outline and Neuration of Wings.-Hesperidae (Pamphilidi).

Drawn in ink by J. H. Emerton from bleached specimeus. Photographie relief-plate prepared by Boston Photogravure Co. The eomplete figures enlarged $\frac{3}{3}$. the others $\frac{2}{1}$. The stigma of the wings of the males is shown as they appear after the bleaching process.

1. Erynnis metca. 11. Atalopedes huron.
2. Pamphila mandan.
3. Phycanassa viator.
4. Ancyloripha numitor.
5. Polites pechius.
6. Amhyscirtes vialis.
7. Calpodes eth7ius.
8. Poanes massasoil.
9. Anthomaster lconardus.
(5. Hylephillt phylarus.
10. Oligoria maculata.
11. Atrytone zabuton.
12. Euphyes metacomet.
13. Thymelicus mystic.
14. Limochores taumas.
15. Thymelicus aetna.
16. Levena accius.
17. Erynnis squsacus.

## EXPLANATION OF PLATE 43.

## Wing patches and folds found in male butterflies.

Figs. 1, 3-s, 10. 11, 13, 16, 17. 20 were trawn in pencil by J. 11. Emerton; figs, 2, 9, 12, 14, 15, by Hemi Metzger. Reproduced photugraphically ly the gelatine process by the Loston Photogravire Co.

1. Erymnis metert $\frac{5}{2}$. Discal stigma of fore wing.
2. Orneis juttu $\frac{1}{1}$. Showing oblique streak across fore wing.
3. Limochores manatequot $\frac{5}{2}$. Discal stigma of fore wing.
4. Hylrphile thyltens $\frac{5}{2}$. Discal stigma of fore wing.
5. Themelicus brettus $\frac{5}{2}$. Discal stigma of fore wing.
6. Thymelieus mystic $\frac{5}{2}$. Diseal stigma of fore wing.
7. Limochores taumas $\frac{5}{2}$. Discal stigma of fore wing.
8. Erymnis manituba $\frac{5}{2}$. Discal stigma of fore wing.
9. Arg!nmis cybele $\frac{1}{4}$. W'ings of one side, showing the apparent thickening of the median branches and submedian rein of the fore wing; aud the row of hairs above the subcostal rein of the hind wing.
10. Limochores pontiar $\frac{5}{2}$. Discal stigma of fore wing.
11. Atatoperles huron $\frac{5}{2}$. Discal stigma of fore wing.
12. Thearens juenalis $\frac{1}{1}$. Showing open costal fold of fore wing.
13. Euphyes metucomet $\frac{5}{2}$. Discal stigna of fore wing.
14. Thymelicus aetno $\frac{5}{2}$. Discal stigina of fore wing.
15. Erymnis sassacus $\frac{5}{2}$. Discal stigma of fore wing.
16. Authomaster leonardus $\frac{5}{2}$. Discal stigua of fore wing.
17. Euphyes rema $\frac{5}{2}$. Discal stigma of fore wing.
18. Polites preckius $\frac{5}{2}$. Diseal stigma of fore wing.
19. Laertias philenor $\frac{1}{1}$. Showing fold of inner margiu of hiud wing, when opened.
20. Lerema accius $\frac{5}{2}$. Discal stigma of fore wing.

## EXPLANATION OF PLATE 44.

## Wing patches and folds found in male butterflies.

After pencil drawings by J. H. Emerton. Reproduced photographically by the gelatine process by the Boston Photogravure Co.

1. Thecla calanus $\frac{35}{1}$. Stigma at upper outer termination of cell, to show the comparative size and arrangement of scales in and about the stigma. The lower margin is toward the apex of the wing.
2. Anosia plexippus $\frac{35}{1}$. Part of the lowest median nervule of left hind wing with its accompanying fold or ponch, concealing the androconia.
3. Anosia plexippus $\frac{35}{1}$. Cross section of the same through the middle of the pouch. Taken from a dry specimen.
4. Speyeria iflalia 150 . Fragment of one of the median veins of fore wing, showing the feathered
androconia mingled with the scales covering the vein. In fresh specimens, the broad scales on the sides of the vein nearly meet over the top and still further conceal the androconia. The lower edge of the figure looks toward the outer margin of the wing.
5. Callidryas eubule $\frac{16}{\frac{1}{1}}$. Showing the patch of erased scales near the base of the second inferior subcostal interspace.
6. Callidryas eubule 150. Part of the base of the same interspace, still further enlarged, to show the diflering form of the raised scales.

## EXPLANATION OF PLATE 45.

## Wing patches and folds found in male butterflies.

From pencil drawings by J. H. Emerton. Reproduced photographically by the gelatiue process by the Boston Photogravure Co.

1. Erynnis sassacus $\frac{30}{1}$.
2. Thanaos brizo $\frac{70}{1}$. Cross section of the costal fold, involving two reins.
3. Thanaos brizo ${ }^{30}$. The same fold opened, the costal edge uppermost.
4. Laertias phitenor $\frac{70}{1}$. A piece from the inner nargin of the upper surface of the left bind wing
(the margin itself at the right), with the fold opened to expose the androconia.
5. Laertias philenor $\frac{70}{1}$. The same, showing a cross section, with the inner flap of the fold turned back to its usual position; the inner edge of the wing is at the left, abore.
6. Thymelicus aetna $\frac{40}{10}$.

## EXPLANATION OF PLATE 46.

## Scales of the male Imago. -- Nymphalidae. Lycaenidae. Papilionidae.

Lithographed by lo. Meiset. All the irawings are by I. Ifenry Blake and are highly manition.

1. Oeneis semidef. From upper surface, fore wing:
2. Orecis jutta. From the oblique streak of the fore wing.
3. Cercyonis mephele. From base of medio-sulbmedian interspace, fore wing.
4. Cissiu purytus. From base of medio-smbmedian interspace, fore wing.
5. Answim plexippus. From the etge of ponch on hind wing.
6. Anmiat pheripurs. From the edge of ponch on hind wing.
7. Anosin pleriphns. From the edge of ponch on hind wiug.
s. Annsir plexipus. From the vein next the pouch.
8. Anusia plecripus. From the interior Hoor of the pouct.
9. Anosin plexippus. From the interior llom of the ponch.
10. Speperin idmlir. From owest median nervule. fore wing.
11. Aromnuis rybple. From Inwest mealian nervale fore wins.
12. Argmmis aphrodite From iowest mediall nervale, fore wing.
13. Arammis athntis. Fron lowest median nerrule, fore wing.
14. Cheridryms uycteis. From base of median interspace, upper surface, fore wing.
15. II!pulus buchananii. From upper surface, fore willg.
16. Calephitis horealis. From upper surface.
17. Thecla fiperons. From discal patch. fore wing.
18. The for onterio. From dincal patch, Lore wing.
19. Threle remerdsii. From discal patch, fore wing.
20. Therle eculicu. From discal pat clı, fore wher.
21. Threle culcmus. From diseal patch, fore wing.
22. Mitura demen. Fion biveal patch, fore wing.
23. Incismlin mugnstws. From discal patch, fore wing.
24. Incismlut irus. From discal patel, fore wins.
25. Incisulit niphom. From diseal pateh, fore wing.
26. Streman tithe. From diocal patch, fore wing.

2s. Nomiales conperi. From upper surface.
2:. Lustirus srndderii. From upper surface.
30. Cymenis psemurgiolus. From upper smrace.
:3. Eteres combutes. From upper surface.
32. Cullidryes eutule. From margin of upper surface lind wing, in the shbucdian interspaces.

3:3. Callidruras entult. From margin of upper surface fore wiug in lower shbestal interspaces.
:3. Chrysophables thofe ' From upper surface.
3.). Epilfomin ppizonthe. Fros upper surface.
31. Wmbthilia nicippe. From near the extremity of the middle median nervals. upger surface, fore wing.
37. Eurymus philndice Formprecobial area, upper surface, hind wing.
:s. Etergmes interior. From precostal area, upper surface, hind wing.
30. I'iors oterecte. From uper surface.
to. Pieris ropae. From nuper surface.
41. Authochuris gemutie. From upper surface
42. Lefretias philenor. From inner side of fold of inner marrein, hind wher.

## EXPLANATION OF PLATE 47.

## Scales peculiar to the male Imago.-Hesperidi.

Lithography by B. Meisel. Drawings by J. Henry Blake. All the drawings are highly magnified. Unless otherwise stated, all the figures under one number are drawn to the same seale.

1. Eudamus proteus: a, clain-bristle from interior of costal fold ; $b, c$, two forms of androconia; $d$, cover-scale from lip of costal fold.
2. Achalarus lycidas: $a$, obspatulate curving androconium; $b$, cover-scale from lip of costal fold; $c$, part of chain-bristle from interior of costal fold.
3. Thanaos persius: $a$, pediform bristle from interior (not so highly magnified as the others); $b$, short androconimm ; $c$, one-pronged rod from interior; $d$, two-pronged rocl from interior; $e$, long androconium ; $f$, cover-scale from lip of costal fold.
4. Thanaos lucilius • $a$, bunch of pediform bristles from interior (not so highly magnified as the others) ; $b$, scaphiform androconium; $c$, long androconium; $l$, one-pronged rod from interior; $e$, seed-shaped androconium; $f$, cover-scale from lip of costal fold.
5. Tharcos juvenalis: $a, b$, two forms of androconia; $c, d$, two forms of cover-scales from lip of costal fold; $e$, pediform bristle from interior (less magnifled than the others).
6. Thanaos icelus: a, cover-scale from lip of costal fold; $b$, seed-shaped androconium ; $c$, scale from inside of lip of costal fold; $d$, flagellate triangular scale from interior; $e$, fabiform androconinm from beneath the costal vein; $f$, cover-scale
from lip of costal fold (of sligbtly different enlargement from the others).
7. Thanaos brizo: a, twisted ribbou from interior; $b$, cover-scale from lip of costal fold ; $c$, coverscale from lip of costal fold (with $f$, of different enlargement from the others) ; $l$, short pointed rod from interior; $e$, long pointerl rod from interior; $f$, straight bristle from interior (with $c$, of different enlargement from the others).
8. Thanans martialis: a, seel-shaped androconium ; $b$, cover-scale from lip of costal fold ; $c$, pediform bristle from interior; $d$, pointed rod from interior.
9. Thanaos terentius: a, ribbon-shaped androconium ; $b$, scaphiform androconium; $c$, seedshaped audroconinm; $d$, fusiform androconinm; $e$, cover-scale from lip of costal fold (of different enlargement from the others) ; $f$, pediform bristle from interior (of independent enlargement).
10. Thanaos horatius: $a, b$, two forms of androconia to same enlargement; $c, d$, two forms of cover-scales from lip of costal fold to same enlargement, but different from preceding; $e$, pediform bristle from interior, independent enlargement.
11. Epargyreus tityrus: $a$, spatulate androconium; $b$, flagellate rod-bristle from interior of costal fold.

## EXPLANATION OF PLATE 4!.

## Scales peculiar to the male Imago.-Pamphilidi.

Lithograply by. Meisel. Irawinga by J. Henry Blake. All the drawings are highly magnitied, those of the same firme to the same degree, mess otherwise specified.

1. Erymnis susvacus; u, from heart of stigma (clifferent enlargenment from the remander) ; $b$. from base of stigma; $c$, from inmer stisma; $d$, from inner stigma; $e$, from upper edge of inner stigma.
2. Erymuis manitala; a, pronged rod from bat sall patch; b, pronged rod from middle patelı; c, bronged rod from apical patelı: $d$, from ineart of stigma; $e$, from beluw basal pateh; ffom ahove outer patelı: $g$. from heart of stigmal (independent enlargement) ; h. Fronn below basal pateli $i$, flom below basal patch; $k$, from below outer patelı; from below the stigma.
3. Ataloperles hurom: a, from above the stigmat b. from upper enge of rater pateh; c. from hasil
patclı; $d$, from leart of stigma; $e$, from tield below stigma: $f$, pronged rod from base of stigma; g. from basal patch ; h, from upper edge of onter patch; $i$, from vitreons spot of lower median inferspace in the female; $k$. pronged rod from basa uf stigma.
4. Limochores tamas; u. pronged rods at base uf stigma; $b$. from field below stigma; $c$, from abore middle of stigma; $d$. from field below stigrma; e, from field below stigma; $f$, from heart of stigua (independent enlarement) ; $g$, from above middle of stigma; $h$. from above middle of tigma: $i$, from above middle of stigna.

## EXPLANATION OF PLATE 50.

## Scales peculiar to the male Imago.-Pamphilidi.

Lithography by B. Meisel. Drawings by J. Heury Blake. All the drawings are highly magnitied, and in the same tigure are drawn to one scale, unless otherwise specified.

1. Thymelicus brettus; a, from field below stigm ma; $b$, from heart of stigma; $c$, from heart of stigma; $d$, from beart of stigma; $e$, from heart of stigma; $f$, from base of stigma; $g$, from base of stigma.
2. Polites pechius; a, from extreme base of stigma; $b$, from base of stigma; $c$, from field below stigma; $d$, from heart of stigma (independent enlargement) ; $e$, from base of stigma; $f$, from heart of stigma (independent enlargement); $g$, from base of stigma; $h$, from extreme base of stigma.
3. Thymelicus mystic; a, from field below stig. ma ; $b$, from heart of stigma (independent enlargement) ; $c$, from beart of stigma; $d$, from extreme base of stigma; $e$, from heart of stigma; $i$, from extreme base of stigma; $g$, from extreme base of stigma.
4. Limochores pontiac; $a$, from extreme base of stigma; $b$, from beart of stigma; $c$, from next the extreme base of stigma; $d$, from field below
stigma; $e$, from field below stigma; $f$, from above extreme tip of stigma; $g$, from above the apical streak; $h$. from the extreme base of the stigma.
5. Limochores manataaqua; a, from field below stigma; $b$, from extreme base of stigma; $c$, from field below stigma; $r l$, from heart of stigma; $e$, from field below stigma; $f$, from heart of stigma (independent enlargement) ; $g$, from above apical streak; $h$, from above apical streak.
6. Euphyes verna; $a$, from extreme base of stigma; $b$, from vitreous spot in lower median interspace of male; $c$. from extreme tip of stigma; d, from ritreous spot in lower median interspace of female; $e$, from extreme tip of stigma; from heart of stigma (independent enlargement); $g$, from extreme tip of stigma; $h$, from extreme tip of stigma; $i$, from extreme tip of stigma; $k$, from extreme tip of stigma; $l$, from extreme tip of stigma.

## EXPLANATION OF PLATE 51.

## Scales peculiar to the male Imago.-Pamphilidi.

Lithography by B. Meisel. Drawings by J. Henry Blake. All the drawings are highly magnified, and in each figure, unless otherwise speeified, are drawn to one seale.

1. Anthomaster leonardus; a, from extreme base of stigma; $b$, from extreme tip of stigma; $c$, from field below stigma; $d$, from field below stigma; $e$, from heart of stigma (independent enlargement) ; $f$, from field below stigma; $g$, from field below stigma; $h$, from extreme base of stigma; $i$, from heart of stigma.
2. Limochores bimucula; $a$, from heart of stigma; $b$, a complete jointed bristle from basal patch, with same enlargement as the rest; $c$, from heart of stigma; $d$, from basal patch; $e$, from lower edge of stigma; $f$, from basal patch; $g$, a cover-scale.
3. Lerema hianna; $a$, from base of stigma; $l$, from tip of stigma; $c$, from tip of stigma; $d$. from base of stigma.
4. Euphyes metacomet; a, from vitreons spot in lower medianinterspace of female; $b$, from base of stigma; c , from base of stigma; $d$, from heart of stigma (independent enlargement).
5. Thymclicus aetna; $a$, from base of stigma; $b$, from base of stigma; $c$, from heart of stigma (independent enlargement); $d$, from field below stigma; $e$, from base of stigma (independent enlargement); $j$, from field below stigma; $g$, from field below stigma; $h$, from tip of stigma; $i$, from tip of stigma; $k$, from centre of stigma.
6. Lerema accius; a, from heart of stigma (independent enlargement); $b$, from above apical streak of stigma; $c$, from stigma; $d$, from the vitreous subcostal spots of the female.

7. Oligoria maculata.

## EXPLANATION OF PLATE 61.

## Anatomical Details of Imago, mostly Extermal

 Burgess; figs. 36, th-48 and in by J. H. bimerton; and the remainder by the anthor:
I. Arymanis apmotite $\frac{1}{1}$ Nemation of hind
2. Arymunis uphrofter $\frac{1}{1}$. Neuration of hind willg. $q$.
3. ('issite pmrytus $\frac{1}{1}$. Nemration of fore wing. $\delta$.

1. Cissiu curytus $\frac{1}{2}$. Nenration of fure wing, o.
2. Thercheruluas $\frac{1}{1}$. Nenration of fore wing. ${ }^{8}$.
3. Therle chluns i. Nenration of fore wing,
4. Chrmsinhumus those $\frac{1}{1}$. Neuration of fore willg. $\delta$.
5. rhrysombemus the $\frac{1}{1}$. Neuration of fore wing, of.
6. Enrymus mhilodice $\frac{1}{1}$. Nenration of fore
wing, ס. Eurgmus mhitodice $\frac{1}{1}$. Nemmation of fore winer $\frac{8}{}$.
7. Cissia curytas $\frac{2}{1}$. Front view of head, denuiled.
8. Cymiris psembergiolus $\frac{2}{1}$. Front view of head, clemucled.
9. Fisumides glawers $\frac{2}{1}$. Front Fiew of head. denmeted.

I4. Epergyrens tit!riss $\frac{2}{1}$. Front view of head. clenuded.
15. Ponilio moly.enes 1. Nemration of fore wing, $\delta$.
16. Pepitionwhyernes $\frac{1}{1}$. Neuration of frre wing. 오.
17. Poly!emin interrogutiomis umbursase 1. Ont-
line of hint wing.
18. Pollygatic intorrogtatiomis folbricii $\frac{1}{1}$. Ontline of hind wing.
19. Polygorial comma dryus i. Outline of hind wing.
20. Pulyfoniou comma hurrisii $\frac{1}{5}$. Outline of hind wing.
21. Polygomire famms $\frac{1}{1}$. Ontline of hind wing.
22. Polygonia gracilis $\frac{1}{1}$. Ontline of himb wing.
23. Polygonia progme l-kryentikn $\frac{1}{2}$. Ontline of hind wing.
24. Polygonia progne r-argentrnm $\frac{1}{1}$. ontline of hincl wing.
25. Brisilarchia archippus $\frac{1}{1}$. Ontlinn of fore wings of a battered specimen, an caught tlying.
26. Cercyonis alope. Papilla of tomgne. inuch cularged.
27. Ciswia earytus. lapilh of tonguc. much enlarged.
28. Basilarchiu urchippus. Papilla of tongue, much enlarged. (The lateral filament is a mistake.)
29. I'anessa atalunta. Papillal of tongue. much enlarged. (Drawn too slenter ant miform.)
30. Junumid coeniu. J'apilla of tongue. much enlargerl.
31. S'peyerice itulia. Papilla of tongue. much enlarged.
32. Argynnis cybele. Papilla of tongue. much enlarged.
33. Basilarchia ast!anax. Papilaa of tongne. much enlarget.
34. Euramessa antiope. Papilla of tomgur, nuch enlarged.
35. I'anessu cardui. P'apilta of tongue. much enlarged. (Drawn with rin thoms too short.)
26. Pulyfoniz finn"s. ('nticular processes of the fool rascomir, mach eularged.
:37. Fenessu atelemter i. Sile view of head and front part of thozas, ciemberl, to show the form and position of the prothoracic lobes and pataria.
88. Inosier plemipus. Marnified crosis section of sale, tos show the striated sarface and the relation of the acale th the mombrane of the wing, bolow.
39. Brenthis myminue l'apilla of tomgue, much chlarged.
40. Phymiontes tharos. l'alpiltat of tonsue, mach enlarged.
41. Chemintuge atrleis. Japilla of tomgne, much enlarged.
42. C'inclitin Jumisii. l'apilla of tonerne, much enlargeal.
43. Euphytryus ${ }^{\text {thurtum. Papilla of tongur. mueh }}$ entargen.
44. Therthe lipurops. l'apilla of tongue. much enlargenl.
45. Jumsir ploripmus. Cuticular processes of the fool reservoir. much enlarged.
46. Polygomit fieumas $\frac{5}{1}$. Sitle view of a part of the digestive tract, to show the relation of the food reserwir to the crop and stomach; the position is the same as in the next figure.
ti. Poluymin fumus $\frac{2}{1}$. Side view of the digestive tract in the ablumen, to show the size relation of the food reservoir (jabout) to the stomach.
ts. Euphoevelos hroilus $\frac{1}{1}$. Vigima of female after pairing, scen from beneatli. The chitinous ribben with its projecting points aud erinkled margin, normally conceated, is torn from its membranous attaehments and left partly protruding.
49. Auosia plexippus $\frac{5}{1}$. End of $\delta$ abiomen, showing the extensile pencil of hairs nearly extruded.

5if. Of neis semidel ? ${ }^{2}$. Sifle view of the digestive tract in the abiomen, to show the size relation of the food reacrooir to the stomach.
51. Strymon titus. 'Tij' of papilla of tongue, much enhared.
it. Pirris rume. Papilla of tongue, much enlarged.
53. Busilurchia restgenux 20. Portion of the tonsue. showing the relations of neighboring pa-
pillae.
at. Temessa crerlui. Extremity of the tongue, showing the disposition of the papillae, enlarged.
nis. Encanessa intiona. Extremity of the tongue, with papillae, culargerl.

Ehi. Euphowedes troilus. Extremity of the tongue, with papillar, enkrererl.
57. Ambluysintes cialis. Extremity of the tongne, with papillae, culared.
58. Amomit plerippus $\frac{\mathrm{y}}{1}$. Extremity of the female abrlomen, site view.
59. Anosiu plecipus $\frac{8}{1}$. Inside lateral view of the walls of the extremity of male abclomen; $h . s$., sheath in which the extensile pencil of hairs is enclosed; rm . tha retracting musele which withdraws it; pr , compare pl. 62 , fig. 4.

## EXPLANATION OF PLATE 62.

## Anatomy of Anosia plexippus.

The original trawings wele male from dissertions of his own ly Mr. Eilwart Burgess, ant most of then putsished (in larger form) in his paper in the Anniversary Memoirs of the Boston Society of Natural llistory, 1880. Fig. 5, however, was manle for this work, from dissections of his own, by Mr. II. II. Emerton.

In all the figures the segments of the thorix are indinated by lioman, of the abdomen by Arabic, nmmeralk.

1. External anatomy of the female butterfy, side view: $a$, antemna; $o$, occiput; $r l$, clypeus; mx, maxilla; $p$, labial palpus; $s$, scutum; sm, scutellum; psm, postscutellum: epm, epimermm; eps, episternum ; cx. coxa; $u$; trochanter; $f$, femur ; all these parts receive a special number indicating the segment of the thorax to which they respectively belong; sp. prothoracic spiracle; $w^{1}, w^{2}$, fore and hind wings; $s p^{3}$, sys, third and cighth pairs of spiracles. Nembranous portions clotted.
2. Internal anatomy of the same, as seen on a side view. (The body wall, trachene and fat borlies are removed). Numerals as before : $1 / h$, plarynx; sel, sgl, salivary duct and gland of right side; oe, oesophagns: $f^{r}$, fool reservoir ; st, stomach; $i$, small intestine: $c$, colon; re rectum; $a$, anus; $m v$, malpighian vessels; $h$, heart or forsal vessel; ao, aorta; uc, aortal chamber; $\quad u$, brain; $\|^{1}$, suboesophareal ganerlion; ty, compound thoracic ganglia; $a g^{\prime}, a g^{4}$, first and fourth aboloninal ganglia; cp , copulatory pouch; $r$, varina; $o$, oviduct; oo, its external opening; r.oc, base of right ovarian tubes turned down to expose the umberlyiug organs; l.ov, left ovarian tubes in position; ov.e, their termination in four corls; s $p^{\prime}$, spermatheca; a.gl', part of the unpaired accessory gland; u.gl ${ }^{2}$, one of the paired
accessory glands, of the other of which only the base is shown. Other letterw as in fig. 1.
3. llorizontal section throngh the extremity of the male abolomen: $p$, penis with its extensor ep, and retractor rp; $p h$, penis bulb; $p s$, slieath; de, ductus ejaculatorius; $h b$, hair bundle cut off; $s m$, intersegmental museles.
4. Lateral view of the same ablomen showing the renitalia in position: $t$, testis; vd, the double ras deferchs; pr, internal process of the ninth scgment, aftiording the attachment of the retractor penis, its posterior wall cut away; $c$, clasp; $f i$, false clasp. other letters as in figs. 2 and 3.
5. Internal anatomy of the female pupa, about three to four days old, as seen on a sitle view. (The lateral wall and tracheae are removed.) : ts, tarsus; er, cremaster. Other letters as in tigs. l. ancl 2.
6. Internal anatomy of the male caterpillar. (The Jody wall, tracheae, fat bodies and muscles of the body wall are removed.) : $s x$, spiuning vessel of one side; $\lambda t$, clorsal ressel: $l$, testis; $s$, spimmeret; soy, subocsoplageal ganglion; uc, nervons cord : $g^{3}, g^{6}, g^{9}$, third, sixth and ninth ganglia. Other letters as in fig. 2. The salivary glands and the convolutions of the malpighian ressels concealing the intestincs are not shown.

## EXPLANATION OF PLATE 63.

## Embryology of Euvanessa antiopa.

Lithographed in three colors by B. Meisel. All the figures are drawn with a camera lucida by C. W. Woodworth from sections abont .00025 inch thick. Figures $1,2,5,7$ and 8 werevarle with a one-fifth, the others with a three-fourths objectire.

1. Section of a small piece of the orariole of a freshly emerged butterfly, showing two eggchambers; $p$, peritoneal membrane; t.p, tunica propria; ep, epithelial cell ; $n$, their nuclei; $e$, eggcell; $g$, germinal vesicle, the nucleus of the egg cell.
2. Section of a single egg chamber considerably further adranced. Lettering the same as in Fig. 1. n. $p$, nutritive process.
3. In oblique section of an egg. showing the migration of the blastoderm cell.-.
4. A section near one end, showing the process of blastoderm formation.
5. Yolk cells, when all but the last row of yolk gramules have degenerated.
6. Section of an egg after the completion of blastoderm formation.
7. Portion of ventral plate, with mesoderm (?) cells.
8. Portion of rentral plate, showing orary cells.
9. Cross section of egg at about the time of the begiuning of the formation of the amuion.
10. Longitudinal section of the same.
11. Section of the egg after the completion of the embryonic membranes; am, amnion; s. $m$, serons membrane.

# EXPLANATION OF PLATE 64. <br> Eggs enlarged and partly in color.-Nymphalidae. 

Printed, by B. Meisel from five stones. All the single eggs slow a side view. Figs. 1, 4, 6. 7, 15, 22, 23, 31, 35, 42 and 43 were drawn by Mary Peart ; fig. 2 by J. 11. Blake; thgs. 3, 5, 8, 9, 14, 16, 17, 21, 25-29, 33, 34, 37-39 and 41 by J. 1I. Emerton; figs. 10, 18-20, 32, 36 and 40 hy S. H. Seudder ; figs. 11 and 30 by A. Assmam; and figs. 12,13 and 24 by L. Trouvelot. Drawings of figs. 6, 1 and 42 were kindly lent by Mr. W. II. Edwards.

1. Anosia plexippus. $\frac{16}{1}$. From an original by Konopicky.
2. Oeneis jutta $\frac{211}{1 .}$. Colored.
3. Cercyonis nephele $\frac{22}{2}$. Plain.
4. Enodia portlandia $\frac{1}{1}$. Outline.
5. Cissict eurytus $\frac{35}{1}$. Plain.
6. Chlorippe clyton ${ }^{2} \frac{1}{1}$. Colored.
7. Chlorippe clyton $\frac{1}{1}$. A cluster on a leaf ; copled from Edwards.
8. Oeneis semidea $\frac{40}{1}$. Plain.
9. Neonympha phocion $\frac{30}{1}$. Plain; from a specimen preserved in glycerine and partly shrunken; restored.
10. Satyrodes eurydice $\frac{20}{1}$. Outline.
11. Cissia purytus $\frac{65}{1}$. Portion of the surface.
12. Basilarchia astyanax $\frac{16}{1}$. Plain.
13. Busilarchia archippus $\frac{20}{1}$. Colored.
14. Junonia coenia $\frac{35}{1}$. Plain; from a specimen in glycerine.
15. Busilarchia arthemis. Colored.
16. Polygonia interrogationis $\frac{6}{1}$. Plain; a lauging pile.
17. Polygonia interrogationis $\frac{25}{1}$. Colored.
18. Polygonia comma $\frac{30}{1}$. Plain.
19. Polygonia comma t. Plain; two piles langing from a leaf.
20. Polygonia comma $\frac{1}{1}$. The same.
21. Polygonia faunus $\frac{35}{1}$. Plain; from a specimen in alcohol.
22. Argymnis allentis $\frac{21}{1}$. Colored; from an original by Konopicky.
23. Euptoiete rlendia. Colored; from an original by Konopicky.
24. Venessa atulanta $\frac{25}{12}$. Colored.
25. Polygonit progne $\frac{35}{1}$. Plain.
26. Euvanessa antiopa $\frac{25}{1}$. Colored.
27. Brenthis bellona $\frac{25}{1}$ P Plain.
28. Brenthis myrina $\frac{25}{1}$. Plain.
29. Phyciodes theros $\frac{1}{1}$. A cluster on an aster leaf, plain.
30. T'enessa cardui ${ }_{1}^{20}$. Plain.
31. Phyriodes tharos $\frac{25}{1}$. Colored.
32. Charidryas mycteis $\frac{30}{1}$. Outline.
33. Euvanessa antiopa $\frac{20}{1}$. A cluster encircling a twig, plain.
34. Speyeria idalia $\frac{30}{1}$. Plain.
35. Aroynnis aphrodite ${ }_{2}^{2}$. Colored; from an original by konopicky.
36. Aglats milberti ${ }^{30}$. Plain.
37. Euphydryas phaeton $\frac{30}{1}$. Colored; the color taken from a drawing by Trouvelot.
38. Brenthis montinus 20. Plain; froun a specimen taken from the body.
39. Argynnis cybele $\frac{30}{1}$. Plain.
40. Aglats milberti $\frac{1}{1}$. A clnster on a nettle leaf, plain.
41. Cinclidia harrisii 40. Colored; an infertile egy.
42. Ifypatus bachmanii $\frac{30}{1}$. Colored.
43. Euphydryas phacton $\frac{1}{1}$. A cluster on a leaf of Chelone; copied from Edwards.

## EXPLANATION OF PLATE 65.

## Eggs enlarged and partly in color.-Lycaeninae, Pierinae.

Printed by B. Meisei from four stones. Figs. 1, 4-6, 11-13, 17, 24, 26, 29, 30 and 32 were drawn by J. H. Emerton; figs. 2, 3, 7, 10 and 23 by A. Assmann; figs. 8 and 20 by J. H. Blake; figs. 9, 14, 15, 22 and 31 by Mrs. Mary Peart; figs. $16,18,19,21$ and 25 by L. Trouvelot; and figs. 27 and 28 by S. II. Scudder. All are highly magnified; the enlargements specified are only approximate.

1. Thecla acadica $\frac{46}{1}$. Plain; side view.
2. Thecla ectwardsii $\frac{50}{1}$. Plain; side view.
3. Thecla calanus $\frac{50}{1}$. Plain; side view.
4. Mitura damon $\frac{63}{1}$. Plain; side view.
5. Uranotes melinus $\frac{500}{1}$. Plain; a part of the surface sculpture.
6. Uranotes melinus $\frac{43}{1}$. Plain; side view.
7. Incisalia niphon $\frac{45}{1}$. Plain; side view.
8. Erora lacta $\frac{50}{1}$. Plain; side view.
9. Incisalia irus $\frac{30}{1}$. Colored; side view.
10. Incisalia itus ${ }_{1}^{38}$. Plain; side view.
11. Strymon titus $\frac{43}{1}$. Ilain; side view.
12. Rusticus scudderii $\frac{45}{1}$. Plain; top riew.
13. Rusticus scudderii $\frac{15}{2}$. Plain; side view.
14. Cyaniris pseudargiolus $\frac{60}{1}$. Plaiu; oblique view.
15. Cyaniris pseudargiolus $\frac{250}{1}$. Plain; a part of the surface sculpture.
16. Epidemia epixanthe $1_{1}^{14}$. Colored; side view
17. Thecla liparops $\frac{54}{1}$, Plain; side view, attached to a twig of shad bush.
18. Cyaniris pseudaraiolus $\frac{20}{1}$. Colored; side view.
19. Chrysophanus thoe $\frac{23}{1}$. Plain; side view.
20. Everes comyntas $\frac{50}{1}$. Plain; oblique view.
21. Heodes hypophlaeas $\frac{35}{1}$. Plain; side view.
22. Eurymus curytheme $\frac{20}{1}$. Colored; side view'.
23. Epidemia cpixanthe $\frac{44}{1}$. Plain; side view.
24. Feniseca tarquinius $\frac{43}{1}$. Plain; side view.
25. Eurymus philodice $\frac{20}{1}$. Plain; side view.
26. Pontia protodice $\frac{30}{1}$. Plain; side view: from a specimen in alcohol.
27. Pieris oleracea $\frac{27}{1}$. Plain; side view.
28. Pieris rapae. $\frac{27}{1}$. Plain; side view.
29. Anthocharis genutia $\frac{46}{1}$. Plain; side view.
30. Callidryas eubule $\frac{28}{1}$. Plain; side view; from a crushed specimen mounted on a slide.
31. Tanthitia nicippe $\frac{20}{1}$. Plain; side riew; from an original drawing by Konopicky.
32. Eurema lisa $\frac{45}{15}$. Plain; side view.

## EXPLANATION OF PLATE 67. Upper Aspect and Micropyles of Eggs.-Nymphalidae.

Printer by B. Mrixel. All the figures are highly magnified. Figa. 1-3. 7, 9. 12. 17, and 18 wore drawn by A. dowmam. Vigs. f, 6, 8, 10, 11, 13-16 ame 19 by J. 1f. Emerton; and Fig. 5l ly lionopicky.

1. Cercyonis ulow. From an empty shell.
2. Śctyrodes curyitice. From an empty shell.
3. Euturessa rention. From an empty sleell; the barl aromol the micropyle was mostly eaten away in the escape of the caterpillar.
t. - Jusia mexiyms. From a specimen mounted in jelly.
\%. Basilarchie methmis.
i. Emtronesset antiopur.
4. V'turssirn custui. From an empty shell.
S. Emptuiete clamdia.
5. Busilurchive urchippls. From all empty shell.
6. Proly!fonior fiemus.
7. Aryynnis cphrodite. From a specimenmounted in jelly.
8. Ar!!!mis rybele. From an empty shell.
9. Argymnis uthatis. From a specimen monnted in jelly, seen from the under surface; the irregular rircle is accidental.
10. Ciumlidia homisii.
11. Phycindes thames.
12. Brenthis momtinus. From a specimen taken from the body and monnted in jelly.
13. Brenthis lellom. From an empty shell.
14. Brenthis myriur. From an empty shell.
15. Apeyeria idotia. From a specimen in jelly.

## EXPLANATION OF PLATE 68.

## Upper Aspect and Micropyles of Eggs.-Lycaenidae. Papilionidae

Printed by B. Meisel. All the figures are highly magnified. Figs. 1, 2. 7. 8, 10, 11, 13-16, 18 and 20 were drawn by A. Assmann; figs. 3. 4, 9, 12, 17 and 19 by J. H. Emerton; fig. 5 by J. H. Blake, and fig. 6 by Mrs. Mary l'eart.

1. Thecle calamus. From an empty shell.
2. Thecla celuardsii. From an empty shell.
3. Uranotes melinus. From a section mounted jelly. in jelly.
4. Strymon titus. From a section mounted in jelly.
5. Everes comyntas. From aliving egg.
6. Cyaniris pseulargiolus.
7. Incisalia miphon. From an empty shell.
8. Incisalia irus. From an emptr shell.
9. Feniseca tarquinius. From a section mounted in jelly.
10. IIeodes hypophlaeas. From an empty shell.
11. Epidemia epixanthe. From a dead specimen.
12. Evers com!mtas. lirom a section mounted in
13. Chrysophanus thoe. From a dead specimen.
14. Eurymus philodice. From an empty shell.
15. Pieris oleracea. From an empty shell.
16. Pieris rapae. From an empty shell.
17. Pieris rapae. From a section mounted in jelly, and far more correct than the preceding.
18. Jrsoniades glaucus. From an empty shell.
19. Heractides cresphontes. From a section mounted in jelly.
20. Euphneades troilus. From an empty shell.

## EXPLANATION OF PLATE 69.

## Upper Aspect and Micropyles of Eggs.-Hesperidae.

Printed by B. Meisel, All the figures are highly marnitied. Firs. 1, 3, 6-9, 11, 12, 14 and 15 were drathon by J. H. Emerton: figs, $4,5,10$ and 13 by A. Assmann; and fig. 2 by S. H. Sonder.

1. Thanaos persius. From a section mounted in jelly and viewed from beneath.
2. Pholisora catullus. Drawn from a living specimen.
3. Thancos lucilius. From a section mounted in jelly, seen from the upper surface.
4. Thunaos brizo. From an empty shell.
5. Thorybes pylades. From an empty shell, from which the parts directly about the mieropyle have been eaten away.
6. Thanaos lucilius. From a section mounted in jelly and viewed from the inner surface.
7. Amblyscirtes vialis. From a sectiou monnted in jelly and viewed from beneath.
8. Aucyloxipha numitor. From a section monnted in jelly anl seen from beneath.
9. Thenaos martialis. From a section mounted in jelly and viewed from beneath.
10. Atrytone zatulon. From an empty shell.
11. Anthomaster leonardus. From a section monnted in jelly and riewed from above.
12. Erynnis sassacus. From a section mounterl in jelly and seen from beneath.
13. Thymelicus mystic. From an empty shell.
14. Limuchores manataqqua. From a section monnted in jelly and viewed from beneath.
15. Calpodes ethlius. From a section mounted in jelly and viewed from above.

## EXPLANATION OF I'LATE TO. <br> Caterpillars at Birth.-Nymphalidae.

HEmerton, dal

## EXPLANATION OF PLATE 71.

## Caterpillars at Birth.-Lycaenidae.

All the drawings are by J. II. Emerton, excepting fig. 3, whieh is by J. H. Blake. Greatly eularged. Printed on stone by B. Meisel.

1. Hearles hypaphlaeas.
2. Theclu liparnps.
3. Mitura damon.
4. Rusticus scudderi. The short bristles on the sides should be small, circular lenticles.
5. Everes comyntas.

## EXPLANATION OF PLATE 7 . <br> Caterpillars at Birth.-Nymphalidae, Papilionidae.

Drawn from nature by J. H. Blake (figs. 2, 3, 4, 7, 8, 11) and J. H. Emerton (figs. 1, 5, 6, 9, 10). Greatly enlarged. Printed on stone by B. Meisel.

1. Cinclidia harrisii.
2. Laertias philenor.
3. Brenthis myrina.
4. Eurymus philodice.
5. Euphoeades troilus.
6. Pieris rapae.
7. Euphoeades troilus. Second stage.
8. Argynnis aphrodite.
9. Phyciodes tharos.
10. Speyeria idalia.
11. Papilio polyxenes.

## EXPLANATION OF PLATE 73. <br> Caterpillars at Birth. -Papilionidae, Hesperidae.

All the drawings are by J. H. Emerton, excepting fig. 3, which is by J. H. Blake. Greatly enlarged. Printed on stone by B. Meisel.

1. Heraclides cresphontes. From a specimen 8. Epargyreus tityrus. mounted in glycerine.
2. Thanaos lucilius.
3. Limachores manataaqua.
4. Ancyloxiph $\alpha$ numitor.
5. Thorybes pylades.
6. Achalarus lycidas.
7. Anthocharis genutia. From a specimen mouuted in balsam.
8. Anthomaster leonardus.
9. Thymelicus aetna.
10. Iphiclides ajax. From a specimen preserved in glycerine.
11. Erynnis sassacus.

# EXPLANATION OF PLATE 74. Caterpillars mostly mature.-Nymphalidae. 

Printed in color from sisteen stones by Julius Bien $\mathbb{A}$ Co. after lawings ly . J. II. Emertun (firs. 2, 6-8, 13, 19, 23 $24.29,3$ ), G. 1. Poujude (figa. 10, 27, 30, 31, 35, 3(i), L. Trumwelot (figs. 4, 17, 24, 26, 34), Mary Peart (figs. 5, 9, 16, Bs) , J. H. Blake (figs. 1, 11, 18), W. Samulers (figs. 3, 14), J. Burekharit (figs. 21, 25), Miss M. E. Blatchford (fig. 32), A. Agassiz (fig. 15), R. II. Streth (fig. 33), C. V. liley (fig. 20), G. Willin (tir. 12), aml S. 11. Scudeler (fig. 22). Figan.

The figures are of natural size and show a side view unless the contrary is mited.

1. Opneis semidea. I'enultinate stage.
2. Ouncis semidea. J)rawn from a blown speeimen with the aid of eolored sketches.
3. Cissin eurytus.
f. Oenris semidere.
4. Inosia ploxippus.
5. Cissia rurytus.
6. Oeneis semider. Jnst hatclred; dorsal vien, enlarucel.
7. Tponympha phocion. From blown specimens and drawincs of Jolan Abbot.
8. Sintyrodes enrydice.
9. Fissiti eurytus. From an alcoholic specinen antl druwings by W. Sannders.
10. Deneis jutta. Just hatched; dorsal view, enlarged.
11. Teunymphat phocion. Copied from Abbot's fignres in the British Muscum.
12. C'issia emytus. Pemultimate stage; dorsal view.
13. Cissia eurytus. Plain and enlarged.
14. Oenris semilere. Dorsal view.
15. Enarlit portlentia.
16. Busilarchia astyonax.
17. Cerryonis alope.
18. Busilarchite urchimus.
19. Chlorippe rlyton. Dorsal view.
20. Basilarrhia ast!anax. Dorsal view.
21. Basifarchio archimpus. Plain ontline, to show the attitude somtimes assumed.
22. Polygomia interoyationis. From a blown specimen.
23. Brssilarchia erchimpus.
24. Busilurchia astyanax. Plain.
25. Basilurchin arthemis.
26. Polygonia interroyretionis. Copiced from $\Delta$ bbut's dhawings in Boisclusal's possession.
2s. Eurrenessa untiopu. From a blown specimen.
27. Junoniu copmia. From a blown specimen.
28. Tumonir coneme. Copied from Ibbot's drawing in Boisdural's possession.
29. Poflyomia progne. Drawn from an alcolnolic specimen, aided by eolored sketches.
30. Polygomirs faumus.
31. Irolygomia satyrus. Jostly dorsal.
32. I'anessa huntera.
33. J'enasse utulantu. From a specimen preserved in alcohol.
34. Iglais milberti. From an alcololic specimen.
35. J'unessucurlui. From a blown speeimen.
36. Pulygomia rumme.

## EXPLANATION OF PLATE ī.

## Caterpillars mostly mature. - Nymphalidae (Argynnidi. Melitaeidi), Lycaenidae.

Printed from stome in eighteen colors hy Julins Bien \& Co. atter painting hy Mra. Mary Peart (fign. 4, 7-11, 13,
 toll (tigs, 2. i, 12, 33, 34, 37, 43), Georve Willis (figs. 21, 24, 32, 41), J. It. Blake (tirs, 27, 30, 36. 35), Mra. Elwards (fig. 17), Miss M. E. Blatchford (tig. 1) and C. V. Riley (fig. 6). Fig.. 8-11, 13, 17, 22, 23, 39 and 45 were kindy lent by W. I1. Edwards, Esq., and tig. 6 by Dr. Riley. Fig. 29, 29, 31, 35 and 4 were by his kind permission copied from the originals in the possession of the late Ir. Boiseluval.

The firure, are of natural size and show a sile view unless otherwise stated.

1. Brmuthis bellona.
2. Brenthis myrinu. From a blown skin. The front pair of spines shonlel not be apically enlarged.
3. Brenthis myrima.
4. Argynmis cybele.
5. Brenthis bellona. View mostly dorsal; not fully grown. After sketches by Miss M. E. Blatehford.
6. Euptoieta rlandia.
7. Euptoreta clundia. Borsal view.
8. Phyriotes tharos. Front view of hearl.
9. Plyciodes tharos. Dursal view.
10. Speypria idtha. Yiew mostly torsal.
11. Euphytryas phupton.
12. Charitryas nyctris. From a blown skin.
13. Cincliatit harrisi. One of the abdominal resments enlarged.
14. Cimblath harisii. From a specimen preserved in alcolol.
1.5. Charilryas myctris. From a specimen about to pupate.
15. Thesta acadica. Dorsal view.
16. Thepla acadira. Dursal view.
17. Thecla uculita. Partly dorsal and partly latcral.
18. IIIputus bachmanii.
19. Thecla calamus. Dorsal view.
20. Urunotes melints. Copied from Abbot's drawine in the British Mnseum, Vol. xvi, fol. 37, tab. 17t.
21. Incisalin irus. Caterpillar eating a plam.
22. Incisnliu irns. The same; dorsai view.
23. Incisulu niphon. Copied from Abbot's painting in the British Museum, Vol. xvi, fol. if, tab. 112.
2.). Therla enturardsii. Dormal view.
24. Thecta calaus. Dorsal view.

2-. Theela lipurous.
2s. Inrisulia ims. Copied from a painting by Abbot in Dr: Boiselural's library.
29. Cyanitis psulurgiolus. Copied from the paintine by Abbot in Dr. Boisduval's library.
30. Mitura domen. Enlarged about $\frac{2}{1}$.
31. Mitura drmon. Copied from the painting by Abbot in De. Boiseluval"s library.
32. Thedf lipurops. View mostly domal. Copied from Abbot's painting in the British MLuseum, Vol. xri, fol. 39, tab. 111.
33. Feniser, turumins. l'emultimate stage, slightly enlarged.
34. Fenisect tarmuinits. Dorsal view.
35. Strymon titus. Copied from the painting by Abbot in Dr. Boistural's library.
36. Rusticus seuhlerii. Third stage, dorsal view, enlarged.
3-. Everes comghters. Dor-al view.
38. Rusticus scmiterii. Much eularged.
39. C'grairis psentergiolus.
40. Cymuris pseulargiolus. Dorsal riew.
41. Fenisec torquinins, Copied from the painting by Abbot in the British Musenm, Vol. xri, fol. 35, tab. so.
42. Heades hypophlaeas. Dorsal view.
43. Fenisect (amumius. A twig of alder covered with plant lice (schizoneura tessellata), in the midat of which is a larva feeding.
44. Errers comyntors. Copied from the painting by Abbot in 1) . Boisdural's library.
4.). Cyumiris pisputurginhus. View mostly dorsal, eularged.

# EXPLANATION OF PLATE 76. <br> Caterpillars, mostly mature.-Papilionidae, Hesperidae (Hesperidi). 

 from the orighal in the possession of the late Dr. Boishluval by his jermisuon.

The figures are of matural size and slmow a side view matess otherwise stated.

1. Eurymus eqrytheme. Eartly doisal, partly lateral.
2. Callidryas equale. Copied from the orisinal by Abhot in Dr. Lioiselavil's fibrary.
3. Euremaliset. Copied from the ariminal ly Abbot in the Gemler collection at the Roston Society of Natmral llistory:
4. Calliclryas rubule. From al blown skin and colorel sketcles made by Jex. A. W. Chapman.
5. Authocharis genutia. From a blown skin.
6. Tanthidia wirimpe.
7. Pontia protodier.
8. Pieris olrrucea.
9. Pieris oleracea.
10. Eurymus phitotice.

I1. Pieris rapae.
12. Pieris rapae.
13. Laertias philenor. From a blown specimen surd descriptions.
14. Iphiclieles ajac. Copied from Nbbot's origimal in the Raddon-Gray collection at the Roston Suclety of Natural llistory.
15. Fisoniades glaucus. Tatien just before pupation.
16. Herarlides cresphontes. From a blown specimen.
17. Papilio polyrenes, In secomitstatere.

Is. Euphofules troilus.
19. Enphupales troilus. Tn third stasie; ulain.
20. Letertias philenor.
21. Laertiasphilenor. Inthird statere; lorsal view.
22. Euphoctetes trwitus. In lhirel stage; flormal vicw.
23. Achalarus lyciates. Dotsal view.
24. I'apilio polyranes. In fomrth stage; dorsal view.
2.5. Thurybes pylades.
26. frasomiades !flourus. Inors:Il view.
27. Papilio polyrenes.
28. Fusomiates !lumens. First stare; much enlarged.
29. Thoryhes pylades. Dotsal view.
30. Fpargyreas tityrus. Partly lorsal, partly latcral view.
31. Epargyreus tityrus. The original was painted in oil un canvas.
32. Thorghes bathyllus. From Abbot's origrinal in the British Musoum, Vol. xvi, fol. 47, tall. I7..
33. Epargyreus tityrus.
3.1. Emlamus protews. From Abhot's originai in the British Musenm, Vol. xvi, fol. 45, tath. 10.
3.). Epargyreus tityrus. In third stage.

## EXPLANATION OF PLATE 77.

## Caterpillars, mostly mature.-Hesperidae.

Printed in eighteen colors by Julius Bien \& Co., after paintings by Mrs. Mary Peart (fiss. 2-5, 10, 21, 23, 20-28, $30-33,35$ ), George Willis (fig. 11, 13, 16, 17, 29), J. H. Emerton (figs. 7, 12, 14, 20, 24, 36), G. A. Poujate (figs. 9, 18, 19, 34), L. Tronvefot (ligs. 6, 22), Mrs. T. L. Mead (fig. 1), Miss M. E. Blathford (ig. 15) and Willian Saunders (fig. 8). I am indebted to W. II. Edwards, Esq., for the kind loan of figs. $1-5.10,21,23,25-25,30-33$ and 35 , and to Mr, Saunders for the gift of fig. S. Figs. 18,19 and $3 t$ were copied, by his permission, from the originals in the late Dr. Boiscuval's possession,

Unless otherwise stated, the tigures are of the mature caterpillar, of the natural size, and show a side view.

1. Thanaos icelus. Partly lateral, partiy clorsai view.
2. Thanaos juvenalis. Front view of head, enlarged.
3. Thanaos juvenalis. Side view of one segment, enlarged.
4. Thanaos jurenalis. Front view of head, fourth stage, enlarged.
5. Thanaos juvenalis. Fourth stage.
6. Thanaos juvenalis.
7. Thanaos persius $\frac{2}{1}$. Dorsal view.
8. Thanaos lucilius. Front view of head.
9. Thanaos lucilius. Drawn from a specimen prescrved in alcoliol, aided by colored sketcbes by W. Saunders.
10. Thanaos juvenalis. Partly lateral, partly dorsal view.
11. Thanaos juvenalis. Copied from Abbot's original in the British Museum, Vol. xvi, fol. 48, tab. 174.
12. Thancos brizo. Fourth stage; dorsal view.
13. Thanaos martialis. Copied from Abbot's original in the British Museum, Vol. xvi, fol. 50, tab. 136.
14. Hesperia montivaga. From a blown specimen lent by C. V. Ritey.
15. Thanaos persius. Dorsal view.
16. Pholisora catullus. Copied from Abbot's orig. inal in the British Mnseum, Vol. xvi, fol. 52, tab. 84 .
17. Hesperia montivaga. Copied from Abbot's
original in the British Museum, Vol, xvi, fol. at, tab. 187.
18. Thanaos brizo, Copied from the original by Abbot in Dr. Boisduval's library.
19. Hylephila phylaeus. Copied from the original by Abbot in Dr. Boisduval's library.
20. Calpodes ethlius. Drawn from a blown specimen and colored after a drawing by Abbot.
21. Pholisora catullus. Fourth stage; partly dorsal, partly lateral riew.
22. Atrytone zabulon.

23, Pholisora catullus.
24. Amblyscirtes vialis.
25. Euphyes rerna.
26. Euphyes verna. Dorsal view.
27. Limochores taumas. Fourth stage.
28. Atalopedes huron.
29. Amblyscirtes samoset. Copicd from the original by Abbot in the British Muscum, Vol. xvi, fol. 53, tab. 85.
30. Atalopedes huron. Third (?) stage; dorsal view.
31. Atulopedes huron.
32. Anthomaster leonardus. First stage.
33. Anthomaster leonardus. Second stage.
34. Thymelicus aetna. Copied from Abbot's original in the library of Dr. Boiscluval.
35. Limochores taumas.
36. Lerema accius. Copied from Abbot and Smith's Lepidopterous iusects of Georgia.

## EXPLANATION OF PLATE 78.

## Front views of Heads of Caterpillars at different Stages.-Nymphalidae.

l'rinted in lithography by 1. Meisel. All the drawines are by J. Menry Blake, excepting fig. 11, whifh is ly H. Metzger, and figs. 12, 13, $1^{7-19,21-23, ~ w h i c h ~ a r e ~ b y ~ M r s . ~ M a r y ~ l e a r t, ~ a n d ~ w e r e ~ k i n d l y ~ l e n t ~ f o r ~ u s e ~ o n ~ t h i s ~ p l a t e ~ b y ~}$ W. II. Edwards, Esq. The enlmgement is wown in most cases by the short line bencath each figure.

1. Anosia plexippus. First stage.
2. Anosia nlexippus. Second stage.
3. Anosir plexipmus. Third stage.
4. Inosir plexippus. Fourth stage.

## EXPLANATION OF PLATE 81.

## Nests and Webs of Caterpillars.-Nymphalidae.

Printed on stone by B. Meisel. Figs, 1-3 and $5-8$ are by S. H. Scudder, and tigs. 4, 9-11 by J. H. Emerton. Ail are of natural sizc.

1. Euvanessa antiopa. Showing the web left on a despoiled twig of elm by the repeated marchings of a colony.
2. Vanessa atalanta. The drooping sewn leaf of a nettle inhabited by the half grown caterpillar, open at the bottom.
3. Aglais milberti. A nest from a nettle leaf opened, to show the manner in which the base is cut before drawing the sides together.
4. Aglais milberti. Nest of a nettle leaf, seen from the side.
5. Basilarchia arthemis. The hiberuaculum formed of a leaf of the cherry birch (the lower leaf of the twig), showing its resemblance to the young spriuging leaf (in the middle), and the bursting bud (at the top) of the same twig.
6. Vanessa atalanta. Base of a nettle leaf which has served as a nest, to show the way in
which it has been eaten at the base, to permit its readier bending.
7. Basilarchia archippus. Manner in which the tip of a willow leaf is eaten by the young eaterpillar.
8. Basilarchia archippus. Another leaf, similarly eaten, with the caterpillar on its perch. The bundle of frass is not shown.
9. Polygonia comma. Concealment of the larva under an elm-leaf, the edges of which, having been deeply cut on either side near the base, are canght together beneath by a few stitches.
10. Vanessa cardui. Nest in a group of thistle leaves.
11. Vanessa huntera. Close nest formed of a mass of petals of Guaphalium entangled in web. See also Pl. 83, fig. 63.

## EXPLANATION OF PLATE 8.

## Nests of Caterpillars. - Nymphalidae (Melitaeidi), Papilioninae. Hesperidae, (Hesperidi).

Printed on stone by B. Meisel. The drawings by J. H. Emerton (figs. 1-f, 8, 9), S. H. Scudder (figs. 7, 10) and C. V.Riley (fig. 11).
I. Thanaos juvenalis. Nest in the partly eaten leaf of the scrub oak.
2. Thanaos juvenalis. A very close nest on a similar leaf, found completely closed at the end of the season and containing a parasitized caterpillar.
3. Euphylryas phaton. The winter nest made of the head of Chelone, as it appears in winter when contracted, and containing an entire colony of partly grown caterpillars.
4. Euphocades troilus. Nest of a leaf of spicebush, made by a caterpillar in its second stage.
5. Euphoeades troilus. A similar nest, made by a caterpillar in its first stage.
6. Euphoeales troilus. A similar nest, made by a caterpillar in its third or fourth stage.
7. Thanars persius. Nest of a poplar leaf, as made by a very young caterpillar.
8. Cinclidia harrisii. Nest formed of the summit leaves of Diplopappus, woven together with a thin web.
9. Epargyreus tityrus. A cocoon found at the base of a tree-trunk and made of coarse saw-dust (the borings of a beetle) entangled in web.
10. Thancos lucilius. Nest of a young caterpillar, made by folding the leaf of columbine.
11. Epargyreus tityrus. Nest formed by fastening together several acljoining leaves of Gleditschia.

## EXPLANATION OF PLATE 83.

## Chrysalids, in color and in outline.-Nymphalidae

Printed in color from sixten stones by Julius Bien © Co., after drawings by J. П. Ennerton (firs. 2, 3, 5, 9, 10, 16, $17,2 \pi, 41,42,44,45,47-50,52,53,5(i-64), 5.11$, Sculder (figs. 18, 19, 21, 22, 24-27,29-32, 34-36), C. A. Poujade (figs, 1, 11, $13,20,39,40,43,51,66,16)$, 1. Trourclot (tign. 4, $37,38,46,54,5 \overline{5}, 65)$, Mr. Mary Peart (tirs. 6, 14, 23). J. MI. Blake (figs. 7. 8), Miss MI. E. Blatchform (fig. 33), C. V. Riley (fig. 15) and Grorge Willis (tig. 19). Figs. 6, 14 and 23 were kiudly lest by Wr. HI. Ehwards, Esrg.

Unless otherwise stated, all the figures are of matural size aud when eolored elrawn tron the living objeet.

1. Anosid plexippus. Site view, drawn from an alcoholic specimen and colored sketches.
2. Amasia plexiputs. side view in outline.
3. Anosit plexippus. Dorsal view in outline.
4. Oeneis semided. Side riew. The abdomen is much too dark.
5. Oeneis semidea. Dorsal view in outline.
6. Enochioportlandia. Side view.
-. Cercyonis nephele. Side view.
7. Cercyonis uphele. Dorsal view in outline.
8. Sutyrodes eurytire. Sille fiew ; drawn from a specimen preserved in alcohol.
9. Teonympho phocion. Side riew; drawn from a dried specimen and dbbot's paintings.
10. Teonmmphit phocion. Side view; copied from Abbot's original in Dr. Boisinval's library.
11. Busilurchiu astyonax. Sirle view; copied from Abbot's original in the British Muscum, Vol. XVI, fol. 23, tab. :3.
12. Busilurchiu ust!onkr. Side view, from a dried specimen.
13. Brsilarchiu arthomis. Sile view.
1.5. (\#borippe clyton. Side view.
14. Chlurippe clyton. Side view in outline.
15. ('hlmipue clyton. Dorsal view in outline.
16. Busiturchiu arflipmas. Ventral view in outline.
17. Busiturchia archippus. Siale.view in outline.
18. Busilurchit archippus. Sitle riew; from a dried sprecimen.
19. Pulymin interrogutionis. Dorsal view in ontline.
20. Polygonio interrogationis. Sicle view in outline.
21. Busilarehiu athemis. Dorsal view in ontline.
22. Polygonia interroyationis. Outline of mesothoracic tuberele from the side.
23. Polygomir interrogutionis. The same, from another -pecimen.
24. Polygonin interrogationis. Ontline of head from in frout, enlarged.
25. Polyfonitr romma. Outline of head from in front, enlirged.
26. Cissia rurylus. Sille view.
27. Polygonia commr. Outline of mesothoracic tubercle from the side.
28. Polytomia comma. The sane, from another specimen.
29. Polygonia foumus. Outline of head from in front, enlarged.
30. Polygonit mome. Outline of head from in front, enlarged.
31. I'olygoniu fumus. Side riew.
32. Polygonia fanmus. Side view in ontline.
33. Polygomit fuunus. Ventral view in ontline.
34. Eugoniz j-album. Ontline of mesothoracic tubercle from the side.
35. Polygonia progne. Side view.
36. Polygonia mogne. Side view.
37. Pelygrnia comma. Side view; copied from Abbot's original in Dr. Boistuval's library.
38. Polygonia interrogntionis. Side view; from a dried specimen.
39. Polygonio sutyrus. Side view; from a dried - pecimen.
40. Pulygonir sat!urs. Ventral view iu outline.
41. Aglais millorti. Side view; from a dried specimen.
42. Eugonia j-album. Side view; from a dried specimen.
43. Enyonia j-album. Ventral riew in outlinc.
44. Polygrmiu +omma. Side view.
45. Polygonin commu. Side view in outliue.
46. I'tlygonin rommu. Dorsal view in outline.
47. Aglais milberti. Sile riew in outline.
48. Alfluis milberti. Dorsal view in outline.
49. Eutanessu entiopa. Side view; from a driedi specimen.
50. T'unessa atalunta. Sitle view in ontline.
51. Trenessa utctente. Dorsal riew in ontline.
52. I'anessu hutera. Side view.
is. I'messat atalanta. side view.
5g. Junoniu coenia. Side view ill outline.
53. Junonir cuenir. Dorsal view in outline.

5s. Eutanessu antionu. Side view in outline.
i9. Eurmessa antiopr. Dorsal view in outline.
60. I'enessar curlut. Side view.
61. ITonessu corlui. Side view in ontline.
62. I'aness curlui. Dorsal view in outline.
63. Tanessit hutera. Dorsal view in outline.
64. Venessulhera. Side riew, langing within a nest formed in captivity immediately before pupation. See also I'l. 81, fig. 11.
6.5. Junonia comia. Side view.
66. Junnia coenia. Side view; copied from Abbot's origiual in Dr. Boisduval's library.
67. Junomiu coenia. Side view; from a dried specimen.

## EXPLANATION OF PLATE St.

## Chrysalids, in color and in outline.-Nymphalidae (Argynnidi, Melitaeidi), Lycaenidae, Pierinae.

 were copied from Abhots oripinds in the possesston of the late 10r. Boistural, hy special permisston.
Unless otherwise stated, all the figures are of natural slze and when wored, Nrawn from the lishag obiget.

1. Argymis cybele. Outlinc, side view.
2. Argtmnis cyhele, Outline, dorsal view,
3. Argymis cubcle. Side view.
4. Speyeria idalia. Side view.
5. Argynnis aphrodite. Sitle view.
(i. Argynuis atlantis. Sille view.
6. Euphydryus phaeton. Silleview.
7. Euptoieta claudia. Side vicw.
8. Euptoicta claulia. Side view.
9. Brenthis bellona. Side view.
10. Brenthis hellona. Side view.
11. Breuthis myrina. Side siew.
12. Brenthis numina. Ontine, side view.
13. Brenthis myrina. Outline, dorsal view.
14. Euphytryas phaston. Outline, site view
15. Euphytryas phartom. Outline, dolsal view.
16. Cinclitia harrisii. Side view.
17. Cinclidia harrisii. Outline. dorsill riew.
18. Charidiyas nycteis. Side view.
19. Phyciodes tharos. Outline, dorsal riew.
20. Phyeindes tharos. Side view.
21. Phyciodes tharns. Side view.
22. Mypatus bachmanii. Side view.
23. Mryatus bachmamii. Side view. Copied from a drawing by Abbot in Dr. Boistural's library
24. Thecla calamus. Side view.
25. Incisclia irus. Side view, cularged.
26. Thecla calanus. Side view.
27. Thecla liparops. Sitie view.
28. Thecla cdenardsii. Side view. Taken from a dead specimen.
29. Mitura damon. Side view. Copied from Abbot's drawiug in Dr. Boisiluval's kibrary.
30. Mitura dimon. Side view, chiarged
31. Incisalia irus. l'ain, dorsal view.
32. Incisalia irus. Phan, side view.
33. Inrisalia irus. Side view. Copied from Ahbot's original in the British Muscum, vol. xvi, fol. 42, tab. 12.
34. Thecta acatice. Site view.
35. Cyaniris pscularyiulus. Side view
36. Strymon titus. Side view. Copied from Ab-
bot's original drawing in Dr. Boishaval's library.
37. Incisalia niphom. Side view. Drawn from : (lead specimen.
38. L'ranotes melimns. Side view. Copied from Abbot's original in the British Museum, vol. xvi, fot. 37, tab. 176.
39. Incisalia niphon. Sule view. Copled from Abhot's drawing in 1)r. Bolsduval's library.
40. Rustirus sculdrii. Side view, enlarged $\frac{3}{1}$.
41. Everes comyntas. Side view. Copied from Abbot's drawing in Dr. Boisduval's library.
42. Cyaniris psendaryiolus. Side view. Copied from Abbot's orisiual in Dr. Boistuval's library ; formerly used in lBnistluval and LeConte's leonomraphy.
43. Cymiris jseudargiolus. Side view, ontline $\frac{\tilde{1}}{}$.
44. Feniseca tarquinius. Side view.
45. Feniseca tarquinius. Side view. Copied from Aboot's original in the British Musemm, vol. xvi, fol. 35, tah. 80.
46. Everes comyntas. Side vicw, enlarged ${ }_{1}^{3}$.
47. Everes comyntas. Side view.
48. Heotes hypophacas. Side view.
49. Chrysophanus thop. Side view. From a dead specimen.
50. Kanthidit nicimpe. Side view.
51. Janthidia nicippe. Ontline, dorsal vicw.
52. Eurymus eurytheme. Side view.
53. Eurymus philodice. Outline, elorsal view.
54. Eurymus philodice. Side view.
55. Eurema lisa. Side view
i-. Pirris oleracea. Side view.
is. Pieris rupac. Side view.
56. Anthocharis !enutia. Site view
57. Callidryas eubule. Side view.
58. Callillyges cubule. Outline, side view.

G2. Callidryas eubule. Outline, dorsal vicw
63. Pieris oleracra. Outlinc, side view.

6t. Pieris sleracea. Outline, dorsal vicw.
G5. Pieris rapaf. Ontline, dorsal view.
lif. Pontia protolier. Outline, torsal views.
(ia. Pontia protulice. Sile view.

## - EXPLANATION OF PLATE 85.

## Chrysalids, in color and in outline-Papilioninae. Hesperidae.

Printel in twenty-one colors by Julius Bien © Co., after drawings by J. 1I. Emerton (figs. 2, 3, 5, 6, 8-10, 12, 15-20. 40, 43. 46, 48), Mrs. Mary Peart (tigs. 11, 21, 27, 36, 41, 44. 47), George Willis (firs. 23, 24, 24, 35, 37, 4.7), G. A. PouJade (tigs. $4,13,28.38,39,42$ ), L. Trouvelot (figs. 1, 7, 22, 2f, 32, 33), S. H. Sender (figs. 30. 31), Mra. Thembre L. Mead (tig. 27), Jacques Burekhardt (fig. 14) and J. H. Blake (fig. 34). Figs. 11, 21, 25, 27, 36. 41, 44 and 47 were kindly lent hy W. 11. Edwards, Esq., and tir. 14 by Dr. Alexaniler Agassiz. As will be seen, a considerable number of the figures of Hesperidac have becu copita foo oriminal drawings made by Abbot in the last eentury.

All the figures are of matural size amd viewed from the side unless the contrary is stated.

1. Jasoniades glaurus.
2. Jasoniades glrurus.
3. Jasoniades glaucus.
4. Jasoniades glaurus. From a deal specimen.
5. Euphoeades troilus. Ontline dorsa! view.
(i. Euphocades troilus. Ontline.
6. Euphoeades troilus. Ontline.
7. Heraclides cresphontes. From a clead specimen.
8. Heractides eresphontes. Outline, Iorsal view.
9. Heraclides ryesphontes. Outline.
10. Iphiclides ajax.
11. Iphiclides ajar. Ontline, flotsal view.
12. Papilio polyrenes. From a dead specimen.
13. Laertias philenor. Dorsal view.
14. Laertias philenor. Ontline, dorsal view.
15. Laertias philenor. Ontline.
16. Laertias philenor. Three juarters view.

From a dead specimen, colored after Abbot and Smith.
18. Papilio polyxenes. Outline, dorsal view.
19. Papilio polyxenes. Outline.
20. Laertias philenor.
21. Achalarus lycidas.
22. Epurgyreus tityrus.
23. Eudamus proters. From the original by Abbot in the British Museum, Vol. xvi, fol. 45 , tab. 10. It has been acedentally put upon the stone back uppermost.
24. Thorybes bathyllus. From Abbot's original in the British museum, Vol. xvi, fol. 47, tab) 173.
25. Eparyyreus titymus.
26. Epargyreus tityrus.
27. Thanaos icelus.
28. Thor!bes pylates.
29. Pholisora catullus. After the oriminal by Abbot in the British Museum, Vol. xvi, fol. 52 , tab. 84.
30. Thanaos lumilius. Ontline.
31. Thamas lucilins. Outline, dorsal vien.
32. Thanaos Iucilius.
33. Thanaos jurenalis.
34. Thanans persius.
35. Hesperia montivaga. After Abbot's original in the British Muscum, Vol. xri. fol. 5t, tab. 137.
36. Pleolisora catullus.
37. Thanaos martialis. From Ibbot's original in the British Museum, Vol. xvi, fol. 50, tab. 136.
38. Thanaos brizo. Copied from Abbot's original in Dr. Boistuval's library.
39. Iylephila phylaeus. Copiel from the same source.
40. Imblyscirtes vialis.
41. Pholisora catuilus. Outline.
42. Thymelicus actno. Copied from the original by Abbot in Dr. Boisduval's library.
43. Atalopedes huron. From a dried speeimen.
44. Limorhores taumas.
45. Amblyscirtes samoset. After the original by Ibbot in the British Mnseum, vol. $\dot{x} v i$, fol. 53, tab. 85.
46. Lerema accius. After Abbot's original in the collection of the Boston Society of Natural Ilistory.
4. Atalopedes huron.
48. Calpodes ethlius. From a dried specimen and drawings by Abbot.

## EXPLANATION OF PLATE 86.

## Anatomical details of early stages, mostly external.

Lithography by B. Meisel. Figs. 2-13, 18, 19, 31, 33-39, 42, 44. 53. 57, 60, 68, 81,83 and 84 were trawn by ITenri Metzger: fiss. $1.1417,26,27,32,40,41,43,45-47,52,54-56,08,59,66$, f7, $69-80$ and 82 by S. H. Seudler; fige. 20-25, 2s-30, $61-6 \mathrm{f}$ by J. H. Emerton; and firs. $48-51$ ly Mrs. Mary Peart, lent by W. H. Edwards, Esq. Figs. 2-12 are copied from Xewport, Phil. trans., 1834 , pl. 15-16, reduced considerably.

1. Anosia plexippus. Main nervons system of the larva.
2. Aglais urticae of Europe. Hain nervons system of the full grown larva.
3. The same, half an hom before changing to a pupa.
4. Thesame, immediately after becoming a pupa.
5. The same, one hour after changing.
6. 'The same, seven hours after changing.
7. The same. twelse hours alter chansing.
8. The same, eighteen hours after changing.
9. The same, twenty-four hours after changing.
10. The same, thirty-six hours after changing.
11. The same, forty-eight hours after changing.
12. The same, fifty-eight hours after clanging.
13. Eurymus philodice. Under surface of last abrlomiual serment of larva.
14. Rustıcus scudderii. Extensile organ on the sides of the eixfth abdominal sesment of the larva.
15. The same. Dermal appendage of the pupa.
16. The same. Dermal appendare of the pupa.
17. Anosia plexippus. Dorsal versel in the posterior lialf of the papa. The figures indicate the abdominal segments, the limits of which are marked by the dotted lines.
18. Oeneis semilea. Under surface of hinder end of pupa, to show the absence of cremastral books.
19. Satyrodes eurydicc. Side view of head of larva.
20. Euphoeades troilus. Some facets of the eye of imago, about $\frac{500}{1}$.
21. The same. 'The eyc of the imago $\frac{16}{1}$.
22. The same. Some half formed facets of the pupal eye, about soe.
23. The same. Ocellar ribbon of the pupa $\frac{16}{1}$.
24. The sane. Ocelli of the larva $\frac{18}{1}$
25. The sime. One ocellus of same, about $\frac{500}{1}$.
26. Eparogreus tityrus. Shronds made by the larva for attachment of the cremastral hooks of the pupa, about $\frac{5}{1}$.
27. Thecla lipurops. Proleg of larva as seeu from above.
28. Thanans lucilius. Egg showing the first attack on the shell by the enclosed larra.
29. The same, fif teen hours later.
30. The same, two hours still later, showing the mandibles at work.
31. Pieris rapae. Prolegs of larva as seen from beneath.
32. Pieris oleracea. Mandible of caterpillar at birth.
33. Heodes hypophlaeas. Dermal appendage of chrysalis.
34, 35. Euphoeudes troilus. Variations in the structure of the ocellar tubercles of the pupa.
34. Pieris rapae. Side view of head and first segment of the thorax of the caterpillar, to show the glandular swelling ou under surface of latter.
35. Anosia plexippus. Side view of head of larva.
36. Satyrodes errydice. Dermal appendage of caterpillar at birth.
37. Cercyonis alope. Dermal appendage of caterpillar at birth.
to. Cissia eurytus. Dermal appendage of caterpillar at birth.
38. The same. Appendage in second stage.
39. Eurymus philodice. Dermal appenclage of caterpill:u at birth.
40. Pieris rapae. Dermal appendage of caterpillar at birth.
41. Pieris oleracea. Dermal appendage of caterpillar at birth.
42. Thorybes pylades. Dermal appendage of caterpillar at birth.

46, 47. Thancos lucilius. Dermalappendages of caterpillar at birth.
48-51. Thanaos juvenalis. Dermal appendages of caterpillar at hirth.
52. Limochores manataaqua. Dermal appendage of caterpillar at birth.
53. Limochores taumas. Dermal appendage of caterpillar at birth.
54. Cinclidia harrisii. Dermal appenclage of caterpillar at birth.
55. The same. Appendage in third stage.
56. The same. Appendage in fourth stage.
57. The same. Appendage in fifth stage.
58. Basilarchia archippus. Dermal appendage of caterpillar at birth.
59. The same. Appendage in second stage.
60. Basilarchia astyanax. Dermal appendage of last stage of larva.
61. Vanessa atalunta. Dermal appendage of first stage of larva.
62. The same. Appendage in second stage.
63. The same. Appendage in third stage.
64. The same. Appendage in fourth stage.
65. The same. Appendage in fifth stage.
66. Aglais milberti. Dermal appendage of fourth stage of larra.
67. Polygonia comma. Dermal appendage of first staqe of larra.
68. Polygonia progne. Dermal appendage of last stage of larva.
69. Vanessa cardui. Dermal appendage of first stage of larya.
70. The same. Appendage in second stage.
71. The same. Appendage in third stage.
72. The same. Appenclage in fourth stage.
73. The same. Appendage in fifth stage.
74. Euphoeades troilus $\frac{1}{1}$. Malformed pupa still carrying part of the larval lead, seen from the right side; r. h., right hemisphere of larval head; $l$. $h$., left hemisphere of same; op., ocellar prominence of chrysalis; s., prothoracic skin.
75. The same, seen from the left side.
76. Head of the last, a little enlarged; o. p., ocellar prominence of chrysalis; $m$. mandibles of larva; l., labium of same.
77. The same; dorsal view, showing larval head on left, ocellar tubercle on right.
78. The same, seen from one side in front and fore-shortened $\frac{1}{1}$.
79. The same as the next, enlarged.
80. The anterior extremity of tig. is, enlarged.
s1. Brenthis myrina. Dermal appendage of full grown larva.
82. Polygonia futnus. Dermal appendage of full grown larva.
83. Ewvanessa antiopa. Dermal appendage of fourth stage of larva.
84. The same. Appendage of full grown larva.

## EXPLANATION OF PLATE ST.

## Miscellaneous Structural Details in all Stages.

All the figmes are borrowed from earlier publications. Figs. 3, 5, 9, 16, 23, and 25 from Mr. Burgess's article in the American naturalist; figs. 14 and 19 from Mr Elwards's paper in the C'madian entomologist; figs. 7 and 20 from Mr. Riley in various publieations; figs. 17 and 18 are coplet] from Mr. IIomgren's paper in the Entomologisk tidskrift; and tig. 22 from Mr. Frohawk's notice in the Entomologist; all the others are from my "Buttertlies." Printed at the University Press, Cambridge.

1. Epargyreus tityrus. Last segment of body $\circ_{f}$ chrysalis, showing (a) the cremaster $\frac{5}{2}$, and (b) the cremastral hook $\frac{25}{1}$.
2. Hamalryres io (of Europe). Undeveloped wing as it appears in the interior of the caterpillar t.
3. Anosiaplexipus. Interior view of the bottom of the head of the imago to show the top of the pharyngeal sac and the muscles which distend it $\frac{10}{1}$. $c l$, elypens; cor, cotnea of the eye; or, oesopha* gus; fim, frontal muscles; dm, dorsal museles; lm, lateral museles; pm, muscles moving the palpus.
4. Eurymus philotice. Ventral view of the front portion of the chrysalis, showing the separate piece (b) covering the base of the tongue $\frac{2}{T}$; $t$, tongue sheath; a antennal sheath; 1,2 , tirst and second pairs of legs.
5. Anosir plexipus. Longitudinal section of the head of imago to show the pharyngeal sac $\frac{20}{1} \cdot m x$, left maxilla (the right removed); mat, floor of mouth cavity or pharyngeal sac; oe, oesophagus; $a v$, oral valve; $s d$, salivary duct; $d m, f m$, dorsal and frontal muscles which open the sac. Above the sac are seen the cut ends of the transversely encircling muscles which close the sac.
6. Euphocades troilus. Ventral view of front portion of clurysalis, showing the sheaths of the various appendages $\frac{2}{1} \cdot t$, tongue sheath; $a$, antennal slieath; 1, 2, first and second pairs of legs. Compare tig. 15.
7. Chloripectyton. Front view of the head of the caterpillar at different stages. $\alpha$, at first stage; $b$, at seconcl; $c$, at third; $d$, at fourth; $e$, at flfth. The natural size is indicated by the lines adjoining.
8. Tenthidia nicippe. Club of antenna of imago, seen from the inner lower side, to show the shallow pits in each joint $\frac{25}{1}$.
9. Anosia plexippus. Longitudinal section of one of the maxillae of the imago to show the interior muscles ( $m$ ) whicl coil it, and the nerve ( $n$ ) and trachea ( $t r$ ) which pass through it. Aloout $\frac{125}{1}$.
10. Anosia plerippus. Side view of front end of caterpillar to show the vesicle on under surface of the first thoracic segment $\frac{2}{1}$, At the right it is seen from beneath and behind, showing the transverse slit at apex.
11. Eprurgyrens titymus. Side view of front end of the chrysalis, showing at * the thoracic spiracle $\underset{1}{2}$.
12. Epargyreus tityrus. Cocoon and chrysalis, the front of the fomer removed to expose the latter
and show the two $Y$-shaped shrouds by which it is suspended $\frac{1}{1}$. Cf. pl. 86, fig. 26.
13. Eucthessecentiopre. Leg of thind thoracie joint of caterpillar seen from behind $\frac{7}{2}$.
14. C'yoniris pseudurgiolus. Extensile organs on the eighth abdominal segment of the eaterpillar $\frac{30}{1}$. $a$, with the spicules expanded; $b$, when partially withdrawn ; $c$, one of the spicules still further enlarged. Cf. tig. 19.
15. Euphoeades troilus. The same as fig. 6 , with the covering of the legs and part of the wing removed on one side, to show how the hind tibia and tarsus are concealed beneath the wings, ontside of the antennae $\frac{2}{1}$.
16. Anosict plexippus. Head of caterpillar seen from beneath $\frac{10}{1}$. $l u$, labrum; mul, mandible; $m x$, maxilla with two palpi; $l m$, labium with one pair of palpi; $s$, spinneret; $u$, antenna (the bristle not shown) ; o, ocelli.
17. Oeneis jutta. C'aterpillar, second stage $\frac{1}{1}$.
18. Oeneis jutto. Caterpillar, third stage $\frac{1}{\frac{1}{4}}$.
19. Cymmisis peudargiolus. Dorsal view of terminal segments of the caterpillar $\frac{6}{1}$. a, spiracles;万, extensile organs ; shown in fig. 14; $c$, transverse vesicle.
20. Anosio plexipus. Showing changes from caterpillar to chrysalis $\frac{1}{1}$. $a$, suspended caterpillar just before rending of the skin; $b$, limp chrysalis, just before the cremaster is withdrawn; $c$, chrysalis just after withdrawal of cremaster. Ideal figures, illustrating the old view of pupation.
21. Eurcnessa antiopa. Proleg of caterpillar; a, seen from the side $\frac{9}{2} ; \quad b$, circlet of hooks at tip, seen from beneath $\frac{5}{1}$; $c$, one of these hooks $\frac{12}{1}$.
22. Thanaos tages (of Europe). Imago at rest for the night on one surface of a heal of grass, which is bowed by its weight.
23. Anosia plecipuis. Cross section of the spiral tongue of the imago, the anterior portion uppermost, to slow the mode in which the two halves unite to fom a central canal through which the fluid food ascends ${ }_{125}^{12}$. $c$, central canal; $t r$, tracheac; $n$, nerves; $m, m^{2}$, muscles of one side.
24. Euphocules troilus. Side riew of head of chrysalis to show the eye. $\frac{2}{1}$.
25. Anosia pifexippas. Front view of denuded head of imago $\frac{10}{1} . o c$, compound eyes; $a$, base of antennae; cl, clypens; $l l$, labrum ; md, mandible, edged with bristles; th, base of maxillae or spiral tongue.

## EXPLANATION OF PLATE 88.

## Hymenopterous Parasites of North American Butterflies.

Lithography by B. Meisel. Figs. $4,5,6,9,10,11,12,14$ and 15 were drawn by George Marx; figs. 3,8 and 13 by James H. Emerton; figs. 1, 2 and 7 by Emerton and Marx, and fig. 16 by Henri Metzger. The enlargement is indicated by the lines at the side.

1. Iclineumon rufiventris.
2. Ichneumon versabilis.
3. Trogus exesorius.
4. Hemiteles humeralis.
5. Limneria limenitidis.
6. Pimpla annulipes.
7. Glypta erratica.
8. Ophion bilineatus.
9. Hoplismenus morulus.
10. Microdus sanctus.
11. Microgaster carinata.
12. Apanteles ylomeratus.
13. Cocoons of Apanteles atalantue.
14. Chalcis flaripes.
15. Chalcis flavipes. llind femur from side.
16. Chrysalis of Polygonia interrogationis, as cut by Hoplismenus morulus in escaping.

## EXPLANATION OF PLATE 89.

## Hymenopterous and Dipterous Parasites of North American Butterflies.

Lithography by B. Meisel. Figs. 1-3, and 12 were lrawu by James H. Emerton; figs. t-9 by George Marx; figs. 10, 14 , and $16-26$ by S. W. Williston; and figs. 11,13 and 1 by Edward Burgess. All the figures are eularged: the eulargement of figs. 1-9 is indiated by the lines at the side of the figure.

## Map of the Great Range, White Mountains, N. H.

This map has been prepared to show the extent of the alpine districts of the White momntains, to illustrate Excursus. I. It is based upou that prepared and published by Mr. W. II. Pickering in his little Walking Guide to the Mt. Weshington Range. His tines have been followed for the contours, streams. paths and forest limits. Some stight additions have been made, and by the use of colors the extent of the forest region and the division of the alpine region into two districts have been clearly shown. The difference in the height of the forest line in different parts of the range, as motified by the exposure or the proximity of deep ravines (first made apparent by the measurements of the late Professor Guyot) are here well brought out, but probably require some modification. The heights of the contour tines are in Euglish feet. The heights of the several mountain summits are taken from Guyots masurements of nearly thirty years ago. Doubtless more correct determinations are foum in Prof. E. C'. Pickering's figures. viz.-Washington, 6293'; Clay, $555 t^{\prime}$; Jefferson, $5736^{\prime}$; Llams, $5819^{\prime}$; Mactison, $5381^{\prime}$; Monroe, 5396 ; Franklin, 4923'; Pleasant, $4781^{\prime}$ (See Appalachia, iv. : 321.)

The path leading to the summit of Mt. Matison from the west branch of the Peabody River should have been marked Osgood Path and not Watson Path.

[^3]:    Imago. Head and appendages as in A. aphrodite. Wings with the upper surface dark orange fulvous, the basal third of the wings slightly infuscated with dusky scales and tawny hairs, but to a much less extent and depth than in aphrodite; markings of both wings precisely the same in general character and position as there, excepting that they are less heavy; they consist in the fore voings of two pairs of sinuous or bent, slender, black bars crossing the cell, each pair partially encircling a fulvous spot; a sickle-shaped black bar at the extremity of the cell ; a mesial, transverse, wholly inter-

[^4]:    * See, however, the generic description.

[^5]:    Imago. Head in front white with a pair of vertical black stripes just within the lateral white edging, above covered with white, blnish white and black hairs. Palpi silvery white, the upper surface black brown, the fringe composed of black hairs without, white hairs within. Antennae with the stalk almost equally annulate with black and white, but the black rather in excess, the chnb black brown, white along the lower onter edge. Thorax covered above with blue white hairs, below a little paler; the legs sordid white, the tibiae annulate above with black.

    Wings above pale, glistcning pruinose blue, with faint greenish reflections, the male having the costal margin very narrowly, the outer margin narrowly, edged with black brown; the female almost wholly dark brown, blackish brown next the extreme edge and powdered heavily with blue scales, which almost entirely conceal the brown next the base but on the outer half of the wing are much more scattered and reach, on the fore wing, only the middle of the outer half of the wing; on the hind wing, however, the outer border, at least toward the anal angle.

    Beneath, uniform, clear, dark slate brown, occasionally with a pallid ray following the interspaces in the outer half of the wing; in both wings there is a circular black

[^6]:    Imago. Head tufted with mingled yetlow and pink tipped, vinous scales and hairs of no great length. Palpi bright yellow, above like the head. Antennae yellowish

[^8]:    of the same plate, $C$. orbis, and the food plant of the catcrpillar, Caesalpina puleherrima, 10 be referred to the same.

[^9]:    Imago. Head moderate, compact; front quadrate, protuberant below, but transversely flat; a mesial, transrerse pit behiud the antennae; vertex in no way tumid, but full posteriorly. Eyes tolerably large and full, naked. Antennae insertel in moderately deep pits, separated by the diameter of the basal joint, slenter, fully as loug as the abdomen, composed of twentr-nine or thirty joints, of which about nine form the slencler, eylindrical, elongated, gradnally incrassated club, which increases very gradually in size up to the antepenultimate joint, and then rapidly tapers to a bluntly rounded apex; the largest joint is about twice as broad as long, or as the stalk, the longer joints of the stalk about three times as long as broad. L'alpi small, the clothing

[^10]:    Imago. Head loosely tufted with very long white bairs mingled with many black ones and with pale lemon yellow hairs and scales behind the eyes; palpi white, with a few black hairs intermingled in the fringe; antemae very pale luteons, rather lightly scaled with white externally, exceptiug the nakel tip of the chub, which is pale luteous, tike the under surface, and excepting also a few scattered brown scales on the club and the parts of the stalk adjoining.

    Wings above chalky white. Fore wings with an arcuate, transverse, blackish brown bar at the extremity of the cell, its convexity outward, with the apex half way to the extremity of the cell, bounded interiorly by a slightly arcuate line at right angles to

[^11]:    ‘pápsos, a stripe.

[^12]:    * óápıб $\mu$ a, dalliance.

[^13]:    *Tyfograpbical error for palatha.

[^14]:    Small, black, compact; abdomen acutely margined along the sides; anteunae arising near the border of the mouth; anterior tibiae with one spur; anterior wings with a marginal and a stigmal rein; antennal club jointed; marginal vein shorter than stigmal; second abdominal segment longest; maxillary palpi 2-jointed; mandibles arcuate, slightly bidentate at apex.

[^15]:    "Length, 1.5 to 2.2 mm . $\delta$ f. Black; palpi white; mandibles sometimes testaceous:
    knees, the four anterior tibiae; the basal half of posterior tibiae, aud ail the tarsi ex-
